I assume this is in reference to the fellow from Singapore who
asked about the XR2211. You basically have it right. The EXAR
data book pretty much will tell him everything there is to know about
the 2211 including in-what-way it is better than the NE567.
Having studied this area extensively, I can also say that I don't
know of anything better than the 2211 for *normal* FSK. Note
that ham radio uses wide-shift FSK, which is a special case.

Jeffrey D. Angus (jangus@skyld.tele.com) wrote:

: Doesn't anyone read books any more?
: Doesn't anyone go the the library and look for something themselves?
: Doesn't anyone look in technical publications for information?

No flame here, but please consider the following:

As a practicing engineer, I find that I can pretty well get whatever information I want by calling a vendor and requesting catalogs or ap notes. Before college, however, information was not that easy to come by. I would not have known how to obtain an Exar data book, for example. Hell, parts were a problem too. I remember pulling resistors out of scrap television sets.

: Are you people really that cheap, lazy or stupid?

Hmmmm..."You people"... what a generality! If that is your impression of the subscribers to this group, feel free to go elsewhere. Consider that the first-time experimenter may want to try out a simple project before he sinks his moola into databooks or the ARRL tome. The local library may not have the databooks he needs.
I have never purchased a component data book in my life (although I do buy the ARRL handbook every few years.) I get them for free. Many times my old ones find homes with budding experimenters. The Heathkit/Lafayette era is gone: homebrewing is almost dead and I feel it needs to be nurtured. I for one will continue to read the messages with titles like: Need help...--You, of course are free to skip them!

: Not that the ARRL amateur radio handbook is the be all to end all,
: but it is two inches thick for a reason. Likewise, QST is loaded
: full of advertisements. (As several others complain about.)

These are valid points, but don't you remember ever getting enthused about a project and wanting the answer NOW? Of course, it is possible to go to the library and get the information in the next day or two, but the net environment is such that someone might have an answer for you in a few hours! Of course, anyone really into the hobby will want a copy of the ARRL handbook, but someone just starting to dabble may bawk at the $25 price tag.

: Dialing 411 (In the US) gets you directory assistance.
Dialing
: 1 (area code) 555-1212 gets you directory assistance for any other
: area code. Dialing 1 800 555-1212 gets you the free number directory
: assistance for those of you too cheap to call someone direct.

What if you don't know the area code? :)

: Now I know there are a lot of obscure technical aspects to amateur
: radio, but geeze people. Get off of your tail ends and look around
: a bit before you waste every one elses time.

Jeff, of course all your points are valid in various degrees, but
try to be a bit more of an Elmer, huh?

: the remark of wasting my time, consider this, I don't think there are
: any stupid questions. But there sure are a lot of unnecessary ones.

Yeah, I'm a Staff Engineer for a Consumer Giant that hires some
engineering fresh-outs from time to time. Not a day goes by that I don't
have similar thoughts. There are many other resources available besides
me for their questions, but it is probably good old human nature that
makes one search the path of immediacy -- sometimes they will be forced
to use the other avenues however -- No matter how many years I practice
engineering the answer is sometimes " I don't know".

We do? I thought 170 Hz was considered narrow shift.

Hams call 170 Hz. "narrow" shift I guess because it is narrow
compared to 850 Hz. shift. That shift was chosen to comply with
FCC regulations forbidding more than 1 kHz. shift. Outside of
the ham community, I don't know of anyone using shifts of more
than 1.5 times the baud rate. A shift of about .8 times the baud
rate is optimum in a bit error rate vs. energy per bit sense.
For 5-bit 60 WPM ham RTTY, the baud rate is only 45.45 baud.
This would imply a shift of 35 to 70 Hz. or so. 170 Hz. is so
wide compared to this that for optimum bandpass filtering, you
need to filter the mark and space frequencies separately and
reject the noise in between. The XR2211 doesn't lend itself to
this scheme.

12. TrakBox panel layout

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-01-03 04:57:27 UTC
From: fmitch@netcom.com
Message-ID: <fmitchCJ1F3s.Iqx@netcom.com>
Source record: 118951

this is a generic reply to all email in response to my trakbox panel
layout post to the usenet and i am also posting this msg on compuserve...

the panel layout is enclosure specific for the Bud LB-1663 Contempo
box... this box is a 'ten-tec' type box, gray in color with black plastic
side panels, with the following dimensions:

3 1/4" high
7 1/32" wide
7 3/16" deep

the box is a mite too small for the pcb to fit into the pcb grooves molded in
the plastic side panels, therefore you have to *trim* the printed circuit
board by about 3/16 ths of an inch... this is easily done with a hand file...
it is *much* easier to do if you haven't populated the board... if you
don't want to trim your pcb you can still use the layout as an
example of "how to do it"...

the current layout is for the switches furnished with the first batch of kits...
the second batch of kits is currently being 'kitted'... the satellite
selector switch for the second batch of kits will be a thumbwheel type...
i am being loaned one of the new type switches and will modify the panel
layout to accomodate either switch...

i will be posting the corel draw file and also a gif file to compuserve as soon
as we have the layout modified for the new type selector switch... (if anyone
needs a different file type please let me know... i can furnish any file type
supported as an export file from corel draw 3) ... look for
a filed named tboxpanl.zip or something similar... a warning on the
gif file --- it looses much detail, and is only useful for you to grab a
quick peek at the layout...

i am looking for a ftp site to upload the files for internet access, any
suggestions for a public accessable location will be appreciated...

if you need the files directly, you can download the zip file from
my data line, see below, or send me a blank, *formatted* disk of any
flavor, along with return postage... i will dump the files on your disk and
mail them back to you...

thanks,

Hello.

I am looking for RF selfs design formulae. While I have some, like the Nagaoka (?), they are not useful in the UHF range. I am especially interested in knowing how to compute the self of a lone silver-layered copper wire, like those found in RF tuners. Can someone help me ?

Thanks.

Vince (Still waiting for my ticket, one month and a day...)

You want to know how to compute the self-resonant frequency of a coil?
("RF selfs"?). The self-resonant frequency will never be higher than
the frequency where the length of the wire is a quarter-wavelength.
Self supporting air wound coils with turns spaced a wire diameter
apart may actually approach this limit. Close wound coils and those
wound on forms will run roughly half this frequency.

Oops. Forgive my rough English. By selfs I meant coils (self-inductances).
I just transposed the French word into English, but it seemed to be a bad
idea :-)

So, there it is back : "Do you know of any formula to compute coils at UHF
frequencies, especially those coils made of a single piece of copper wire".

Thanks and excuse me for the mistake.

Vince.

I remember needing large amounts of resistors, caps, and pots for some projects I did in high school and college; got most of them "free for the asking" from the manufacturer. In fact, I once got a free transformer custom-wound for me (wanted dual secondaries, center-tapped each, one for a +/-5V supply and one for a +/-12V supply, of substantial current capability)! Tactic was simple:

"To: Marketing Department
XYZ Corp.
WhoKnowsWhere, USA

Dear Sir/Madame:

I am a (college or high school) student working on an electrical engineering project relating to . . . .

I am in need of some components which your company manufactures:

. . . . .
. . . . .
. . . . .

Any help would be greatly appreciated.

Thanx,

Joe Blow"

For one project I needed a BUNCH of 1% resistors; sent letters to 2 vendors, got parts from BOTH (had my pick of carbon comp or metal film, guess which I chose)!

Remember:
IT NEVER HURTS TO ASK!

>

Wire parallel to infinite Ground Plate

The impedance is

Z0 ~= 138 * log (D/d) where d is the diameter of the wire,
and D is the height above the ground
log in base 10

Now find the line length that will resonance with C at Fequency f

Length= (waveleght/(2*pi))* arctan(1/(Z0*2*pi*f*C))
where wavelength = Speed of light / f
C is the capacitance

Example:

A #20 AWG wire is 0.25" above ground will be resonated with
a 10 pf capacitor. The operationg fequency is 433 MHz.
What is the require leghth of the wire ?

Answer is = 3.2 cm or 1.25"

0.032" is d for #20 AWG
Z0 is 123 ohms

<------ 3.2 cm ---------> 10pF

---------------------------||-
| | ^
| | 0.25"
== Ground

In TV turner, they use square box surround the wire,
the equation for the square coaxial is

Z0 ~= 138 log (1.178 * D / d)

Ref: VHF/UHF Manual by G.R.Jessop G6JP
Published by RSGB

NOW: Can someone tell me how to tap the wire for for 50 ohms point ?

It's a Siliconix part. I think J310 is the same thing in a plastic
package, if you don't need the metal can.

Correct

: Is it my imagination, or is the noise on the plastic packages much higher
: than the metal can equivalents?

I think it's your imagination. I can imagine that the plastic case could possibly cause increased 1/f noise (low-frequency) due to surface contamination, but at VHF frequencies, the performance should be the same.

Van-

I had one of the early Weather Cubes from Radio Shack. They were very simple VHF receivers, with a variable-frequency local oscillator. If you had the appropriate plastic alignment tool, it was simple to re-tune the osillator and antenna coils to work on Two Meters. However, they were lousey receivers.

If there is a NEW Weather Cube, it may be crystal-controlled like the other more recent weather receivers. I have one that is about 5 years old, that uses a single crystal with a switch for the three weather frequencies. Each switch position warps the crystal oscillator to the appropriate frequency. It is far superior to the old Weather Cube!

To use the crystal-controlled weather receivers on Two Meters, it would be necessary to change the crystal. To figure the frequency, subtract the existing crystal's frequency from the weather channel frequency (which one?), to determine the intermediate frequency. (If it happens to be 10.7 MHz, you may be able to use common scanner crystals.) Then, add or subtract the IF to/from your Two Meter frequency, to determine a new crystal frequency.

The weather band is far enough away from Two Meters, to require retuning of the RF stages.

hello.
I'm rather new at this (just thought i'd let you know up front).
anyway, i'm working on a shortwave superhet reciever (which uses the
TDA7000 IC chip) and, now that i'm all done, it doesn't work. I've checked
the thing 2 or 3 times now (its driving me crazy). Here is where my problem
may be: i don't know where to anchor the -12V lead. :\ The schematic i have
does not include the negative lead (i suppose i should *know* where it goes).
I hooked it to ground and, obvioulsy, got a short (my batteries were glowin'
red; i.e. they became extremely hot). The audio output seems, to me, to just
be the output from a capacitor or three (loud at first, no signal, then
gradually dies down). The other radios have the negative lead going to
a tap from one of the toroid coils...but that doesn't work for me. BTW,
it is a 455-kHz superhet IF circuit with varactor-tuned coils.
i'd appreciate any help i could get. thanks in advance.

23. Optimum FSK shift

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-01-03 23:51:25 UTC
From: rkarlqu@scd.hp.com
Message-ID: <2gab1t$5v2@hpscit.sc.hp.com>
Source record: 118962

I mentioned in passing that an FSK shift of .8 times the baud rate is optimum in the sense of minimizing BER vs. Eb/No. This seems to have raised a few eyebrows around here (even famous netizen Gary Coffman was surprised to hear this). I would like to go into some detail about this for you skeptics out there.

For incoherently detected FSK (as is done in ham radio), the minimum shift that will give orthogonality is a shift equal to the baud rate. For coherently detected FSK, the minimum shift that will give orthogonality is half the baud rate. This shift is commonly called "Minimum Shift Keying (MSK)" and is normally used with coherent detection. Shifts that are any integral multiple of half the baud rate are also orthogonal. In between shifts are not orthogonal.

Orthogonality (loosely speaking) means that the mark and space tones don't interfere with each other (I don't want to get too mathematical here).

It turns out that a shift of about .75 to .8 times the baud rate, although it is not orthogonal, gives the lowest bit error rate (BER) for a given energy per bit to noise spectral density ratio (Eb/No). Eb/No is proportional to S/N (signal to noise ratio), by the way. Even though it is a disadvantage to be non-orthogonal, the extra shift increases the detected signal more than enough to compensate for it. The optimum shift is .83 dB. better than the orthogonal shifts. Wider shifts are suboptimal because the receiver filter has to be wider and takes in more noise.

For "60 WPM" 5 bit RTTY, where the baud rate is 45.45, the shifts discussed above would be:

Minimum shift keying: 22.73 Hz.
Optimum shift keying: 34 Hz.
Minimum shift for orthogonality with non-coherent detection: 45.45 Hz.

In a communications theory sense, there is no reason to use more than 45.45 Hz. shift at 60 WPM. The only reason for using a ridiculously wide shift of 170 Hz. (or even 850 Hz.) is the frequency stability issue (admittedly a real issue). One way of partially fixing this problem is to detect the mark and space tones separately as ASK signals with separate narrow filters for each one.

[stuff deleted, said it was mostly the same]

It's not your imagination, *if* you're running at high input impedances (like I do, making condenser mic innards, input Z > 1.5 G ohms). In most cases, the American black plastic used for injection molding these cases is rather leaky. A few tens or hundreds of megohms, but of course that's way too much leakage current (ideal = 0, or less). Some of the Japanese makers have it right and have a black plastic that's opaque enough to prevent photons from reaching the junction but with enough insulation between the particles of pigment that no current flows. Some nuclear instrumentation types use metal can fets and saw off the can so they can clean the surface of the die, reporting significant improvement from this process.

I'll agree with your comments for the case of an IC whose input
is both tones; however, for the case of designs that use seperate
filters and detectors, this is true only where the filters are
narrow enough to be able to get them that close to the same freq.

170 hz and wider shifts are used in no small part because the Q
of such things as 66 mh toroids make it hard to keep the other
tone out of the detector for its tone. Further, in this design,
the noise is that in the bandwidth of each tone filter and does
result in significantly better proformance than the cheaper.to.build
IC-Single-Filter method.

Which circuit are you using? The "Explorer" HF receiver by Paul Daulton (73 Amateur Radio Aug. '92) has pin 16 as ground (presumably for -12V supply and signal). Try to look this article up- it may have some valuable clues for you.

I am not sure about current availability of Siliconix U310 (canned).
But you can probably use J310 (plastic-molded) as well, which you can
find easily. See ads of RF PARTS in QST for example. Also Sony's
2SK125 can be used in place of J310.

The same chips are used for U310 and J310.

Input capacitances which may change NF matching condition are same
(according to the data sheets).

If someone had experienced much worse NF for J310 than for U310, the
pin connections might have been the problem:-) Their pin connections
are a little confusing.

I'm not skeptical at all of MSK, Richard, it has a clear advantage in the presence of pure Gaussian noise. The Heatherington modem uses it. It's just that "narrow shift" for ordinary FSK of the type used on HF normally means 170 Hz. I was also somewhat startled to see you say that only hams used a shift as wide as 170 Hz for 45.45 baud RTTY. Commercial wire service signals use either 450 Hz or 850 Hz. Multiplex RTTY and SITOR also typically use wider shifts than 170 Hz. I'll talk about why below.

>In a communications theory sense, there is no reason to use more
>than 45.45 Hz. shift at 60 WPM. The only reason for using a
>ridiculously wide shift of 170 Hz. (or even 850 Hz.) is the
>frequency stability issue (admittedly a real issue). One way of
>partially fixing this problem is to detect the mark and space
>tones separately as ASK signals with separate narrow filters for
>each one.

Now the discussion of why a wider shift may be better at HF than the "optimum" shift. While frequency stabliity for autostart operations may be a consideration with simple detectors, the real reason is the nature of the channel errors at HF. The source of channel errors at HF is rarely Gaussian noise, so the BER advantage of MSK in Gaussian noise is usually moot.

Most channel errors at HF are burst errors caused by impulse type noises, selective fading, or interference. By using a wide shift, separate mark and space filters, and a soft decision circuit, it's possible to maintain solid copy even though mark or space may be momentarily obliterated by a channel error. That's why PLL type detectors are generally inferior to filter type detectors for HF RTTY. They only have one filter, necessarily of channel width, which exposes them to more sources of channel error than two very narrow filters with suitable decision networks staggered for mark and space detection. An error anywhere in the bandwidth unlocks the PLL, but the filter detector continues to work as long as it copies either mark or space.

By use of synchronous oversampling, extremely narrow mark and space filters can be synthesized. They aren't optimum from the standpoint

of recovering maximum signal energy vis Gaussian noise, but that's
a good trade at HF where other sources of error predominate and signal
levels are usually fairly high.

Rich:

I am afraid that I am in agreement with Gary. You do not give an argument
that this shift is the `best.' You state that it is. ALL good TU's, both
analog and DSP use the approach Gary mentions. By having a wider seperation,
with filters narrow (determined by baud rate, Nyquist or otherwise), the
NOISE performance of the TU can be made the same, but you do get the diversity
enhancement Gary mentioned. AEA, HAL, and others all use the sliding slicer
that helps fix up selective fading. Selective fading is easier to handle if
the tones are more widely seperated. Another factor that begins to enter
is the characteristics of the filters in your radio which all the arguments
to date have neglected I think. I wish to see a likelihood derivation before
I believe your claim. The ham that operates simtel-20, Keith ???, whose
call I can't remember, wrote the seminal paper almost 25 years ago that
details the sliding slicer approach now used by AEA, HAL, etc.

What you say is generally true. However, if 170 Hz. is good for this
reason, 850 Hz. ought to be even better. Funny you don't hear much 850
anymore. (Yes I know, its not politically correct because it wastes
spectrum). In any event, outside of the HF world, the AWGN model generally
applies. (AWGN= additive white gaussian noise).

Anyway, we're getting into semantics here. The system you are describing
(which is a good system to be sure) could also be described as ASK
(amplitude shift keying) with 2-fold diversity. You could just as well
send out two optimum FSK signals (with .8*baud rate shift) spaced 850 Hz.
apart), 3 dB down. I suspect that would give even better performance
because of the 3 dB advantage of FSK over ASK. However, I don't suppose the
FCC would let you do that in the ham bands :-).

If the transmitter and receiver use matched filters, the optimum
-6dB bandwidth is equal to the baud rate (45.45 Hz. in the 60 WPM
5 bit example). This is known as the Nyquist bandwidth.

The same die in the can will probably have a lower noise figure than
the plastic version of that device becuase the metal can provides
a better thermal path and therefore a lower die temperature.

I think what I said has been misinterpreted. If you use an FSK detector
(not two ASK detectors), then this shift is best. You are right that I
don't give an argument why it is best; that argument is in the reference
and is too complicated to post here. The original discussion involved using
an XR2211 as an FSK detector, and for that case the .8*baud rate shift is
optimum for AWGN.

>that helps fix up selective fading. Selective fading is easier to handle if
>the tones are more widely seperated. Another factor that begins to enter

It seems to me that selective fading should be minimized if the tones are
very close in frequency. Any disagreement?

>to date have neglected I think. I wish to see a likelihood derivation before
>I believe your claim.

The derivation is in the reference. In fact, the derivation is in many
books on data transmission. Again, the derivation is for AWGN channels only.
Funny HF effects may change the results.

{ a good thread on HF data modems }
I've been interested in this subject for some time. The only
reference that I've been able to find on HF data modems is an article in
Communications Quarterly about 2 years ago by Dr. Chandler of AEA. He
talks about both the soft detection and the dual filters.

Anyway, I was wondering if anyone knew of a currently available book
on this subject. Most texts on data communications via radio these days
(at least the ones I've seen) deal with M-ary signaling at microwave
frequencies. Is there a reference on simple FSK modems at HF ?

I am sensitive to the concerns about using USENET without first looking
elsewhere :-).

Thanks

Yes wider shifts are better. In fact *very* wide shift, IE spread
spectrum, is even better yet for dealing with the kinds of channel
errors that plague HF. (SS is, of course, more than just a wide shift,
but the diversity argument still holds.) Outside of HF, there isn't
much RTTY activity, so Gaussian noise performance is not too applicable.
(I'm ignoring VHF/UHF packet, though similar techniques apply to it. In
practice at VHF/UHF most of it is strong signal AFSK now anyway. The
only exception is satellite use, and Gaussian noise criteria would be
appropriate there, but doppler makes very narrow shifts a practical
problem.)

>Anyway, we're getting into semantics here. The system you are describing

>FCC would let you do that in the ham bands :-).

I do believe it's legal now, though it didn't used to be, to have more
than one transmitter operating on the same band at the same time. Redundancy
is the secret to robustness. Having correlated signals spread over a wider
bandwidth gives better channel error immunity with the kinds of error sources
at HF. Other forms of redundancy, such as FEC, are also good.

>>By use of synchronous oversampling, extremely narrow mark and space

>5 bit example). This is known as the Nyquist bandwidth.

You can use sub-Nyquist filtering if you can tolerate the loss of
signal energy and bit smearing that such filtering implies. At HF
you almost always can. The point I'm trying to make here is that
it's a mistake to use Gaussian noise performance criteria for a
medium where Gaussian noise isn't the primary problem.

This is far from the situation in which U310/J310s are used for low noise *RF* frontend. Optimum NF matching to 50 ohm input line is much easier for grounded gate configuration because it offers nearly optimum input impedance (~100 ohm) without matching circuit. Broadband NF matching can be achieved by just paralleling a pair of JFETs.

I think that the point you're missing about selective fading is that if your signal is too narrow (MSK) when the selective fade drifts across you, you're gone. Period. With the 170 Hz shift and two detectors the selective fade usually dosen't hit both tones at the same time. (Hence the magic name selective fading.)

45. 457 KHz Avalanche Tranceiver

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-01-05 21:34:10 UTC
From: trotter@allegra.att.com
Message-ID: <1994Jan5.213410.20654@ulysses.att.com>
Source record: 118783

I'd like to make an avalanche tranceiver and I wonder if anyone
has either a circuit for a homebrew one or can point me in the
direction of any information on such a device?

The avalanche tranciever is a tranciever that operates on 457 KHz
in continuous transmit mode until you need to use it then you
turn it onto receive in order to find the unfortunate person who
is burried (and who still has their tranceiver on transmit). While
I could probably think of a reasonably good circuit for this myself
I'd perfer to use a "tested" design given its potential use. I
could buy one - but they cost about $300 which seems very expensive
for what it is.

So any information on a design or where I might get information
or a circuit diagram would be greatly appreciated!

Thanks,
John

>Like I said originally, if 170 is so good, 850 ought to be even better.
>So why did everyone change from 850 to 170?

850 Hz is better, but the PLL detector came along in cheap manufactured
equipment and didn't work well with the wide shift for the reasons
you stated in the original exchange. Most hams didn't understand
why they were using wide shift, nyquist limits and associated math
were impressive buzzwords to them, and the idea that narrow is better
was easily accepted because of their early CW brainwashing. :-) (Narrow
really is better for CW.) So they had no trouble changing over to the
newer equipment with it's narrow shift. There were other factors too.
At about the same time, HF radios were changing over to SSB transceivers
and RTTY started using AFSK tones into the SSB transmitters. Since early
SSB rigs had filters that weren't phase or amplitude linear for spit,
wide shift didn't work very well through them. The older rigs were CW
rigs that were direct FSKed, and receivers used LC filtering that had
a soft response curve that worked well with the wider shift. Even Nyquist
showed in 1928 that a cosine response was best for FSK reception.

Many old timers have noted the reduced performance of the newer equipment,
but either never knew, or forgot, why the wider shift was better. If they
complained, it was either about the perceived worse band conditions, or the
shoddy performance of solid state equipment. They were snowed by arguments
put forth by manufacturers and the amateur press, such as the one you made,
that the narrow shift was better. Those arguments are even true if the issue
is Gaussian noise, but at HF that's not the problem.

Irv Hoff explained it all very well in his series of articles in QST
back in the late 60s. Some of that is reproduced in the 1975 ARRL book
Specialized Communications Techniques for the Radio Amateur. The primary
source of channel errors at HF is not that of weak signals buried in
Gaussian noise. Rather it is impulse noises, selective fading, and
adjacent channel interference.

48. Rebuilding a Heath Warrior RF amp.

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-01-06 04:47:43 UTC
From: gcouger@olesun.okstate.edu
Message-ID: <1994Jan6.044743.18733@osuunx.ucc.okstate.edu>
Source record: 118786

I have aquired a Heath Kit Warior Amp. 4 parralel 811A's. It seems the high voltage Transformer is shorted. It is a center tapped 3,400 volts at about 600 to 700 ma. I plan to replace the gas tube rectifiers with 3 1 or 2 amp 1kv diodes.

Any ideas and past ecperiance with making this a better amp and a source for transformer either 1700 v or 3400 v center tapped would be appricated. I am planing to put a -100 volts or so grid bias cutoff to shut the tubes down on recieve. I would like to use it for pactor which needs some pretty fast switching. The time can be adjusted for the change over to a fairly long time.

My first thought is to leave the antenna hooked to the output of the amp at all times and hook the reciver to the antenna with a normal open realy. Build a sequencer that when the ptt line is activated blocks the grid on the Amp and switch the reciver in. When the ptt drops the reciver antenna is shorted to ground, the grid unblocked and the xmiter on. I expect that it will take some logic in the ttl line to trap it and do the proper sequence before the ptt is passed on to the xciver.

All comments welcome. I will summerize if the response warrents it.

Thanks
Gordon

>Like I said originally, if 170 is so good, 850 ought to be even better.
>So why did everyone change from 850 to 170?

Well I'll take a stab at that, without climbing upstairs to review old
issues of RTTY circa 1960 first.

We started out with 850 because that was the military standard - remember
the AN/FGC-1? - and that was probably because drifty receivers like the
SP-600, etc. are fairly intolerable with much less. For the same reason
we didn't do much operating at 20 meters and above, because our transmitters
were the kind where the VFO was on 80 or 160 and multiplied to get to
the higher frequency bands, so the drift was multiplied too. Actually
the military standard 850 probably was derived from a pre-world-war-II
operation by Press Wireless and friends.

Anyway, when SSB became popular the amateur transmitters and receivers
were improved in frequency stability; and then we could think about using
narrower shift. It seemed like the humane thing to do, cut down on the
apparent bandwidth of our signals. 170 was chosen because, I think,
there was a whole series of off-the-shelf carrier telegraph filters with
frequencies spaced at multiples of 170 - that's where 850 came from.
And being able to operate 170 implied that your transmitter and receiver
were good enough for the job, hence something to brag about.

Few if any of the early TUs actually took advantage of the frequency
diversity of wide shift anyway. Most of them had an input bandpass
filter, a limiter, and then a discriminator or pair of filters with
detectors taking the difference of the two filter outputs. Someone
pointed out that if you're going to use a limiter then a linear discriminator
is better than the nonlinear one you get with a couple of sharp filters
under certain conditions I don't remember. The theory of detecting
on-off keyed signals, and then combining the results of two channels
in frequency diversity, was never very well brought out in the amateur
literature.

Then too, a lot of hams used TUs of simple design, entirely adequate
for AFSK operation on VHF; but they used then at HF and depended on
the selectivity of the receiver for pre-limiter bandpass filtering.
Better TUs designed specifically for HF almost always had their own
input filters. I remember we discussed a lot whether the filter
should be flat over the passband or should be more of a comb filter,
with peaks at the mark and space frequencies and a dip in between.
I don't know if anyone ever really made filters both ways and compared
them.

Then too, besides QRM and selective fading we've got multipath
to think about...

Source record: 118790

Greetings and Happy New Year!

I am interested in obtaining information about thermoelectric devices called Peltier Diodes (junctions?). My extremely limited understanding of these devices is that at low voltage DC they act as unidirectional heat pumps, and have been used in electric cooler units with suitable heat sinks and "cold" sinks on the heat energy input side. Since I am NOT an electrical engineer (a botanist/professor actually) I'd appreciate any information the engineers among you might have as to how these devices work (practically, not theoretically!), how they are rated, and if possible, how to use them in constructing cooler units. These might be useful for improving efficiency of power supply heat sinks?? but honestly, my ulterior motive is in the construction of a cool-chamber in which to store my homebrew beers!! As a ham with a very small modicum of electronics background (pretty damn small!), I've been asked by some fellow homebrewers to investigate these beasts, and try to prototype some "homebrew" coolers for our homebrews (pretty neat, eh?).
If any of you have information about these Peltier devices, application notes,m thermal ratings, recommendations for installation/increasing efficiency, etc. I'd be (actually WE'D be) very appreciative to learn about these, or at least sources where we could get more information. Thanks in advance for your help....

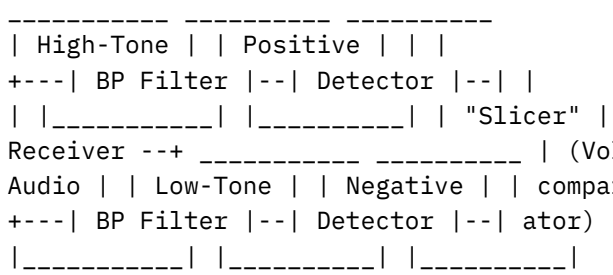
Right.

I think there were two reasons for switching to 170 Hz shift. One was to
reduce interference / allow space for more channels per band.

The other was to allow narrower IF filtering. With 850 Hz, you had to
use your SSB filter, around 2.5 kHz wide. With 170 Hz shift, you could
switch in your CW filter, generally 400 or 500 Hz wide. This gave a big
advantage in interference rejection.

I don't think most amateur TU's (TU = Terminal Unit = demodulator)
got much benefit from diversity anyway. Typical block diagram:



Sometimes post-detection low pass filters would be included as well.

I looked into manufacturing these a while ago and corresponded with
some folks who answered a query on rec.backcountry. You can get them
for about $200 from REI and other discounters. They need to be not
only 457 kHz but 2.275 kHz also for the old style receivers that are
still in use here in the US some places. The technology is very
primitive. However even with a good design I don't think I would like
to field test one in actual use without a backup.

Take a look at the ARRL QRP Classics book; it has a bunch of designs of varying complexity. Also, if you have a library which has back issues of QST, take a look through them. There's many designs in there which don't make it into the anthology-type books.

I'm trying to build a 3 channel audio mixer to
take 8 ohm output from 3 receivers and "blend"
it to a common 8 ohm bus. Using three LM386's, when I
connect the outputs they go into oscillation.
I've tried power supply from 5v to 12v and put
all the spec sheets bypass capacitors in. The
configuration is minimum gain (i.e. 20) with
no external gain resistors.

If I try to isolate the 386's with small ohmage
resistors between outputs, I get bad freq response.

Anyone have any suggestions or design source books?
Tnx,

Ned Hamilton, AB6FI

Howdy,
Try mixing on the input -- resistive divider, then using *one* amplifier to
drive the bus.

Cheers,
Carl

Also try putting 8 ohm resistors across the three radio outputs so the radios see an 8 ohm load. Then use a resistive mixer on the input of one LM386.
An attempt art a diagram:

```
RADIO OUTPUT----------|----------|
/ / 25-50K pot
8 ohms \ \
/ /<--------/\/\/\/\/\-------|
\ \ 10K |
/ / . |----- TO LM386
GROUND----------------|----------| . |
. . . |
. . . .
. . . .
As many more sections as needed.... From other sections
. . . .
. . . .
```

I use this to make cheap recordings off of guitar amps, but I use a speaker instead of an 8 ohm resistor.
I've only had five inputs at max, so I'm not sure how many you can actually put on before you load down the input of the LM386 (in this case).
I use an LF353 to do the summing/amp'ing.

Amateur radio is really the way to go on this one. If you transmit at a randomly selected frequency you are likely to get in trouble with the Canadian counterpart to the US Federal Communications Commission. You might interfere with the radios the fire fighters use to talk to each other, or whatever. Or you could mess up some radiotelescope that is listening to faint signals from some distant place.

If you study for, and get, an amateur radio license you will learn the frequencies at which amateurs are permitted to transmit, the permitted power levels, and so on. And you will enter a community that includes people who would gladly help you learn more.

Good luck.

Have been building the Campbell R2 receiver. I have some Mini-Circuits SRA-1 mixers on hand, but I'm uncertain of the detailed specs. My 1988 ARRL handbook says it has LO/RF range of 5-500 MHz, but my Radiokit catalog (reliable source?!) says 0.5-500 MHz. May want to run it on 80 meters someday, so I'd like to know which is right.

Also, the pinout the guy gave me was the same as the SBL-1. Can anyone confirm this?

Okay, I'm going to even things up by agreeing with Rick. :-) Actually, the paper which first derived the optimum shift, if I recall rightly, concluded that it was about 0.72. It depends somewhat on the filter characteristics - I think that paper assumed Butterworth of a fairly low order. In any case, the optimum is in the 0.6 - 0.8 range. It's certainly true that the wider-shift systems will often outperform an FSK system with "optimum" modulation index on a selective fading channel, but as Rick correctly points out, they are dual-diversity ASK systems, so it's an apples and oranges comparison. On the other hand, if I were designing an FSK system (not AFSK, of course) for a link at VHF/UHF, I would aim for a modulation index of around 0.7... all things being equal, it *would* be near the optimum in this application.

Hi - I have a couple of projects rambling around in my head that seem easy enought to build - but I have know idea on how to start them!

1) I, like many no-coders have a HT (yeasu ft-470.) Now, I think a useful gadget to build would be a phone patch for obvious reasons...
Any plans/hints on how to get going? Nothing fancy really needed; a control operator would be present to dial the phone, etc.

2) A personal repeater type thing for simplex. Again, using the HT, a little gadget that one could hook up, record a little bit of voice (say 30 secs) and then retransmit when the frequency is clear. 30 Secs is a short time, but would be useful in emergencies, etc.

Thanks for any help/plans!

This is called a *simpatch*, and commercially available units exist.
Basically it uses a sampling technique, listening for 0.1 sec out of
each second to determine when you key up, and transfers from transmission
to reception automatically when it detects your carrier. This leaves you
in control. Typically these units are controlled by touchtones and allow
outdialing only. Note that this is classed as auxillary operation and
requires you to operate at 222 MHz or higher.

>2) A personal repeater type thing for simplex. Again, using the HT, a little

This is called a *simpeater* and is also commercially available. This
system uses digital voice storage techniques.

Gary

What do you mean with "FSK" vs. "ASK" detector ? A Travis
discriminator is usualy considered a FM discriminator i.e. a FSK
discriminator, but it is not more and not less as a pair of AM
detectors associated with a pair of resonant circuits tuned to
slightly different frequencies. In his very interesting serie of
articles in Wireless World, 1957, G.G. Johnstone demonstrated that
the Foster-Seeley discriminator can be considered as equivalent to
the Travis discriminator.

The XR2211 is different. It is a Phase Locked Loop circuit having
properties somewhat different from discriminators like the ones of
the Travis, Foster-Seeley or Ratio-Detector type. Is a PLL a "more"
FSK type discriminator than the above mentioned ones ?

Does the preceding limiter make the difference ?

OKay, I'm an old timer. I worked RTTY using 850 Hz shift as well as
170 Hz. My practical experience showed me that the 170 Hz is a good
shift for RTTY, better than the 850 Hz shift. The main reason is
that a narrower filter can be used with good results. 350 to 500 Hz
is a good bandwidth for the 170 Hz shift system. As smaller as the
bandwith is, as smaller is the probability that an interference occurs in
this bandwidth. Further, a narrow bandwidth reduces the effect of
selective QSB. As Irv Hoff noted in the 60s in his interesting serie
of articles in QST, the main problem in RTTY receiving is QRM and
QSB, not gaussian noise. My own experience showed me, that QRM is
usually a more severe problem than QSB. The 170 Hz shift allows an

oscillator drift according to the usually encountred oscillator
properties.

A very rough (and not scientific) guess would be 30 feet up the tower.
Diameter of the shunt line will change the impedance - doesn't matter
much I don't think. Just make it match with your series gamma capacitor.

76. Portable 2m Antenna for Mountaineering???

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-01-11 22:01:29 UTC
From: mercer@dgs.dnd.ca
Message-ID: <2gv7jp$3e0@netfs.dnd.ca>

Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

I am an avid climber/backpacker etc and want to be able to use my HT in the backcountry. I require a design for an antenna (with better gain than my rubber duck) that is light, easily packable, and not too bulky, which will allow me to work repeaters in the 2m band. In case it matters, most (but not all) of the use will be from mountain tops.

Obviously, a 1/2 wave diapole is a candidate but I was wondering if there are any others?

How about a boom that can be disassembeled? A flexable J pole? I would appreciate any and all suggestions.

Thanks
DAve

Obviously a roled up twinlead J-pole will offer better performance than
the rubber dummy load, and it's easy to carry in the pack. However, if
you're really in the back country, a collapsable beam will be much better.
Simple designs based on folding elements from common TV antennas are
available. You can slip the folded antenna into a PVC tube and use that
as a walking stick. When you're ready to operate, the PVC can double as
a short mast.

You can consider the filter response a cascade of the receiver first IF filter and the filters in the demodulator if you can guarantee that the first IF isn't overloaded (a non-trivial problem with some of today's receivers). That means you can achieve an effective bandwidth of around 35 Hz with a filter mode demodulator even if your receiver filter is 1 kHz. Running with AGC disabled, and use of front end attenuators as required, must be assumed for effective RTTY operation. (Note: if you use audio derived AGC, from the filter outputs, you can use some slow AGC to follow gradual fades.)

I'd recommend an AEA Hot Rod (tm) antenna or similar.
Its a half-wave vertical (so no ground radials required) that
fits onto an HT BNC, telescopes down to about 8 inches long.
(There's one laying somewhere on the Continental Divide Trail,
where I dropped it.:-)

2nd choice is a j-pole made out of TV twinlead. Not really that
great unless there are usually trees around to hang it in.
Even then its probably too much hassle for the hiking/backpacking
scenario.

There are beams that disassemble, but unless you really need the
few dB of gain and are going to stay put for a while, I'd say
they are too much hassle as well.

About the Peltier elements. There is only one company I know making these things, it is Melcor, somewhere in the USA. They make Peltier elements from 0.32 W (a few millimeters size) up to 120 W (62 by 62 mm). The problem with Peltier element is low efficiency, less than 50 per cent and low operating voltage (around 0.5 V per element). Melcor specifies maximum temperature difference 65 ... 70 degrees (Celsius or Kelvin), but elements are much more effective with lower difference. Maximum temperature is 110 degrees Celsius.

There are commercial ice boxes for cars and boats using Peltier elements. Peltier elements are common in cooling CCD elements and other semiconductors down to -70 degrees Celsius. Elements can be cascaded for higher temperature difference.

Melcor Peltier elements are thin (2.7 ... 5.6 mm) ceramic squares with metallic surfaces. One gets becomes cool, other hot. The positive and negative terminals and thus cool and hot surfaces are defined in Melcor Peltier elements. In a generic Peltier element, you can change the polarity and thus cold and hot surfaces.

The small element, 0.32 W (code 618-718) is A$64.19 (about US$40), the large one, 120 W (code 284-826) is A$272.98 (about US$190).

I've been using a J-pole for years now.. it's made of 1/4 inch Al, and
breaks down into 3 x 1/4 wavelength sections. When I go tramping (hiking)
into areas where rptr coverage is marginal, I just strap the thing to the
side of my pack (slip it inside my compression straps). Takes less than
a minute to take it off the side of the pack and assemble it, and it
weighs next to nothing. The antenna has survived fairly rough treatment,
and is still going strong. I've decided that the extra hassles involved
in carrying a beam (ie extra weight and bulk) are not justified; the
J-pole is also easily repairable should any damage occur.
What I am now looking for is a rugged dual band antenna design (no radials)
that I can break down and throw onto the pack. Any suggestions??? Some of the
hills around here reflect UHF signals into the valleys much better thhan 2m
ones, though generally, attenuation in the bush on 70cm seems to be a lot
greater than at 2m.

cheers,
Dave, ZL2BHE.

David,

Try a rolled up J-pole. It's made of 300 Ohm Twin lead and tapped with a
50 Ohm coax with BNC connector on opposite end. It provides about 2.8dB
gain. You can buy the ant from MFJ for about $12 or build it yourself.
The dimensions are below:

```
-- for 146MHz center freq
|
|
|
|
this side |
56" |
| | <---------------------------------- trim here for best SWR.
| | 14" on this side
| |
coax====> - - 1-3/4" tap from bottom
| |
---
```

I've experimented with lots of these with good results (built about 30 or so
for myself, friends, and local HAM classes).

Good luck and 73,
Tom

Hi there ,

I got possession of this instrument but not manual (user nor owner)

WAYNE KERR
Automatic Component Bridge
B605

I think this is used to measure C and L and R but not completly sure.
It has 4 boards (logic,analogic,supply and display) built more or less
in 1984 I guess. It has a pod where to place the component under measurement
connected to the mainframe with 2 coax cable plus another cable with a jack
with two contact at the mainframe end.

The other problem is that the LCD of it ,I think, is not working
so I am looking for the schematics of this object other than
the user's manual.
I will pay xerox and shipment if somebody can help me suppling
them to me.
Last question: is Wayne Kerr still in the
buisness so that I could ask to them for some help.

Thanks to anybody that will reply to me I prefer email directly
to me at robertov@hqlab.ico.olivetti.com

Since a J-pole is an end-fed 1/2 wave vertical, how does it have
2.8 dB of gain? 2.8dB of gain in relation to what? A quarter-wave?
A dipole? An isotropic radiator?

Optimally, a J-pole will have 0 dB relative to a 1/2 wave dipole,
but the matching section contributes loss, so I'd normally expect
a J-pole to provide a little less than 0dB, say -.5dB relative
to a dipole. If so, this is something like 1.5dB over an isotropic
radiator...

>slightly different frequencies. In his very interesting serie of

Well in a typical FSK receiving setup you have the bandwidth of the receiver, and then perhaps a bandpass filter (which might be flat-topped or two-peaked), and then a limiter, and then the pair of tuned circuits which constitute a discriminator. In this case FM limiter capture takes effect, so whatever signal is strongest at the input to the limiter will dominate the output. I don't know if any theoretical work has been done about the concepts of non-flat-bandpass pre-limiter filtering, or on nonlinear discriminators.

On the other hand, you might have a non-limiting path from the receiver output through a pair of filters, each with an amplitude detector; and you don't necessarily combine the detector outputs by simply subtracting. You might, for instance, use logic such that if both detectors say mark you output mark; if both say space you output space; if they don't agree you output mark. Or you might decide which to believe by seeing which recently had the stronger signal.

TUs of both kinds have been built, or TUs where the limiter can be switched off. As I recall the limiter on gives best results if you can keep the desired signal stronger than the interference; and the limiter-off gives better performance when the desired signal is weak, but usually at that point copy is so crummy anyway that you might as well give up.

I did some experimenting years ago with positive feedback around the limiter and its input filter. There were some papers by Elie J. Baghdady of MIT in the late 1950s on this topic which suggested that the best performance was to be had with just enough positive feedback around the limiter to cause oscillation in the absence of input. (IEEE Transactions on Communication, if I remember correctly) I didn't have the smarts nor the test facilities to make any measurements you could hang your hat on; but it did seem qualitatively that the feedback helped.

There are some FM video demodulator IC's that were introduced a few years ago (by Philips or Plessey, I can't remember for sure) that used oscillating limiter front ends followed by PLLs. They had substantially lower thresholds that most other demods when used for TVRO receivers. So I think Baghdady's paper (March 1958 Proc. IRE, I believe) has some validity. By the way, it was based on an earlier (1956?) Baghdady paper that was based on a ~1953 paper by some other author.

However, it is not obvious to me that threshold effect is relevant to FSK reception.

There was a TAB book published in the early 80s called something like "The Complete Guide to FM Repeaters," by Bill Pasternak WA6ITF and someone else.

Like most TAB books, it has its load of typos, misidentified figures, and misinformation, but it does have a chapter on converting the 13-509 to repeater service. Dunno if it's still in print, though.

You might also check out the "220 Notes" publication that comes (came) out of Chicago. That had lots of articles on 13-509 mods.

I have hiked several times with my Cushcraft 4 element 2 meter beam. If you need the extra gain from a beam, it works great and is not overly bulky to carry if you pack it into a tube or keep it in the original box. I use wingnuts to speed the assembly process and have a portable tripod to mount the thing. It's sort of home-brewed out of a similar design I saw in the ARRL handbook. Anyway, like someone else said here, the AEA Hotrod is a great little telescopic antenna that outperforms a duck several times over.

First a simple question:
Does any know where I can find the spec for gerber files ?
I want to write a converter from gerber to interface to an
ancient Houson Instruments DMP-5 plotter.

Now a more involved, and totally unrelated question:
I have a Yaesu drop in charger (NC-29), these have a terrible
reputation for frying NiCad packs, so I was thinking of replacing
the charging circuit with something better. Does anyone have
any favourite designs they've built in the past ?

I was also wondering if anyone knows the secret of the 4 srping
contacts that mate with the battery pack, my 12V pack has 3
contacts on it, and my 7.2V pack only has 2. I've not traced out
the circuit yet, so it may become self-evident when I do that.

One last question (I promise):
Does Fluke (in the US) have a spare parts phone number ? I've
got an old Fluke DMM, with a cracked LCD display that I'd like
to fix.

Thanks, I'll summarise answers to nay or all questions if there's interest.

>

Well I'm not so avid, but I'd like to be. Make the roll-up J-pole.
Around here, the mountain tops are where the repeaters ARE, so I
look for a better signal from the bottom of the Gorge.

Hey maybe you could load up a variety of wired nuts and see if any
might present a match???

I have a vintage FT401 that I aquired while in Japan. I know there was a version of the FT101 that used a pair of 6146s for finals. I would like to convert the FT401 that I have to 6146 finals. If anyone has the data available or a schematic for the FT101 that used the 6146 finals. I would sure appreciate a copy.

I'm planning to construct a 1 watt, 2 meter transceiver for 9600 baud packet.
Before I went and reinvented the wheel I thought I'd see if anyone else
out there has already covered this ground.

If this is something new, would anyone care to speculate as to the market
for such an item?

I'll tackle this. The NC-29 is a straight timed charger, and will indeed fry batteries that aren't fully discharged. It'll also reset it's timer and give *another* full charge to the battery if there's a bump on the power line. Definitely not good. Yaesu has a newer charger, the NC-42, that solves these problems, but it's not intended for FT-470 packs. If you take a dremel tool, or a knife, and whittle away the plastic rib on the inner side of the charger pocket, FT-470 batteries will fit in, and be properly charged.

If you want to rebuild the NC-29 instead, the best circuit is a pulse charger that samples cell voltage between pulses and shuts off when it sees the small voltage sag that occurs as the battery reaches full charge. This is only a few millivolts, and needs to be read under a moderate load. There was a circuit in QST a while back.

> any favourite designs they've built in the past ?
>
Common 3 terminal voltage regulators (e.g. LM317,780X) can be wired as constant current sources and make excellent NiCad chargers. Here is an example:

```
.................
Vin . .Vout Diode
......... LM 317 ..............|\|......+
. . . |/|
.................. .
.Vref > To
. > R Battery
. >
. .
..................
.............................................-
```

Set R so that the battery will charge at 10% of it's full amp-hour capacity.

If your battery is rated at 1 Amp Hour, then you want to change it at 100ma for 12 hours (the 2 extra hours make up for loss). R will be Vref / current needed. Vref for a LM317 is 1.25V. So R would be 1.25V / .1A = 12.5 ohms.

The diode is there to keep current going into the battery (not visa versa).

Voltage into the circuit must at least equal the required regulator overhead (typically 2V) + Vref + V(diode drop) + battery voltage.

The components must be rated to handle the power dissipation based on specific charging requirements.

100. Need Repair Info for Monitor

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-01-14 16:53:40 UTC
From: steveh@hpcvra.cv.hp.com
Message-ID: <-299209999@hpcvra.cv.hp.com>
Source record: 118888

A few years ago, I bought a new Commodore C-64 for the kids, hoping they would play a few games and get interested in computers... What happened was, they got interested in computer games... Anyway, a couple of years went by, and the nice little Samsung composite color monitor that we bought with the system just up and died. Being an EE myself and having lots of test equipment at work, I could easily fix most little problems that crop up in such devices, IF I only had a schematic and maybe a little block diagram and some repair info. The kids aren't too interested anymore, and I might set up a dedicated packet station or something if I could get it fixed...

So, the question for the netters is: Where does one obtain this sort of information for this sort of equipment? I have heard that Sams Co. provides such stuff. Does any one know a phone and address for them? Do they provide a catalog or something? My suspicion is that the manufacturer would want to give you a thick manual that costs its weight in platinum and only covers one model (and probably hasn't been translated from Japanese), if you can even find the right contact in the company. I really would hate to throw this thing in the junk pile (I have more than enough CRT bombs lying around already). Thanks for any help!

I am planning on building a frequency converter for my TH28 handheld
that will convert 36-54MHz to 136-154MHz. Has anyone done this? It's
seems like it should be pretty easy to do, but I wanted to try and get
some input on the subject before I started. I'm thinking of using a
NE602 double balanced mixer/oscillator as the heart of the project with
100Mhz for the LO. I'm sure someone has done this before, I just want to
get some ideas. If anyone can help me, It would be greatly appreciated.

Thanks,

Sean

Sean Norris snorris@trumpet.aix.calpoly.edu

The NE602 makes a lousy front end. Sure, it is compact and it does provide a simple solution, but it wasn't designed to deal with signals of a wide dynamic range, as you might encounter with low-band VHF.

Instead, I'd suggest you use dual-gate FET, or maybe even a JFET preamp feeding a diode mixer. In either case, use a JFET xtal LO. The diode mixer requires more LO injection than the dual-gate MOSFET; it probably is overkill. Be sure to put a reasonable filter on the front end; a low-pass/high-pass with a few poles each would probably be more than enough to suppress what little bit of image energy you'd encounter in the 236-254Mhz band. The only other problem you'll have to deal with will be IF feedthrough in the 136-154Mhz band; the DBM mixer helps a bunch with this but the NE602 is liable to overload, particularly with the wide band receiver. I guess a diode mixer would be the best solution for this...

Revision: 1.5 12/18/93 14:15:53
Changes: new mailing lists, .packet rmgroup, and .policy updates

(Note: The following is reprinted with the permission of the author.)

This message describes the rec.radio.amateur.*, rec.radio.cb, rec.radio.info,
and rec.radio.swap newsgroups. It is intended to serve as a guide for the new
reader on what to find where. Questions and comments may be directed to the
author, Jay Maynard, K5ZC, by Internet electronic mail at
jmaynard@oac.hsc.uth.tmc.edu. This message was last changed on 18 September
1993 to add the mailing lists for the new rec.radio.amateur newsgroups, to
note the rmgroup of rec.radio.amateur.packet, and to officially retire some
(in)famous threads of discussion on rec.radio.amateur.policy.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list
for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions
were held on the mailing list, and sent to the mailboxes of those who had
signed up for it. When the Usenet software was created, and net news as we
now know it was developed, a newsgroup was created for hams: net.ham-radio.
The mailing list and the newsgroup were gatewayed together, eventually.

As the net grew, and as packet radio came into vogue, packet discussion began
to dominate other topics in the group and on the list. This resulted in the
logical solution: a group was created to hold the packet discussion, and
another corresponding mailing list was created as well: net.ham-radio.packet
and PACKET-RADIO, respectively.

These two groups served for several years, and went through Usenet's Great
Renaming essentially unchanged, moving from net.ham-radio[.packet] to
rec.ham-radio[.packet]. Readership and volume grew with the rest of the
network.

The INFO-HAMS mailing list was originally run from a US Army computer at
White Sands Missile Range, SIMTEL20. There were few problems with this
arrangement, but one was that the system was not supposed to be used for
commercial purposes. Since one of hams' favorite pastimes is swapping
gear, it was natural for hams to post messages about equipment for sale
to INFO-HAMS/rec.ham-radio. This ran afoul of SIMTEL20's no-commercial-use
restriction, and after some argument, a group was created specifically
```

for messages like that: rec.ham-radio.swap. This group wasn't gatewayed to a mailing list, thus avoiding problems.

While all this was happening, other folks wanted to discuss other aspects of the world of radio than the personal communications services. Those folks created the rec.radio.shortwave and rec.radio.noncomm newsgroups, and established the precedent of the rec.radio.* hierarchy, which in turn reflected Usenet's overall trend toward a hierarchical name structure.

The debate between proponents of a no-code ham radio license and its opponents grew fierce and voluminous in late 1989 and 1990. Eventually, both sides grew weary of the debate, and those who had not been involved even more so. A proposal for a newsgroup dedicated to licensing issues failed. A later proposal was made for a group that would cover the many recurring legal issues discussions. During discussion of the latter proposal, it became clear that it would be desirable to fit the ham radio groups under the rec.radio.* hierarchy. A full-blown reorganization was passed by Usenet voters in January 1991, leading to the overall structure we now use.

After the reorganization, more and more regular information postings began to appear, and were spread out across the various groups in rec.radio.*. Taking the successful example of the news.answers group, where informational postings from across the net are sent, the group rec.radio.info was created in December, 1992, with Mark Salyzyn, VE6MGS, initially serving as moderator.

In January, 1993, many users started complaining about the volume in rec.radio.amateur.misc. This led to a discussion about a second reorganization, which sparked the creation of a mailing list by Ian Kluft, KD6EUI. This list, which was eventually joined by many of the most prolific posters to the ham radio groups, came up with a proposal to add 11 groups to the rec.radio.amateur hierarchy in April 1993. The subsequent vote, held in May and early June, approved the creation of five groups: rec.radio.amateur.digital.misc (to replace .packet), .equipment, .homebrew, .antenna, and .space.

The Current Groups

I can hear you asking, "OK, so this is all neat history, but what does it have to do with me now?" The answer is that the history of each group has a direct bearing on what the group is used for, and what's considered appropriate where.

The easy one is rec.radio.amateur.misc. It is what rec.ham-radio was renamed to during the reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize

this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, should be removed by September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is now rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there.

The first reorganization added two groups to the list, one of which is rec.radio.amateur.policy. This group was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The other added group is rec.radio.cb. This is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently Mark Salyzyn, VE6MGS. The email address for submissions to the group is rec-radio-info@ve6mgs.ampr.ab.ca. Inquires and other administrivia should be directed to rec-radio-request@ve6mgs.ampr.ab.ca. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas,

commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

Just open 'em up and see what's going on inside. Most of these types of monitors are completed automated assembly except for the flyback trans. My Commodore monitor died when the lead that hadn't been soldered finally got gungy enough to not conduct anymore.

>and someone else.
^^^^^^^^^^^

I'm the someone else. I did 11 chapters in the book, and
some of 5 more. It was book number 1212.

>Like most TAB books, it has its load of typos, misidentified figures, and
^^^^^^^^^^^^^
Like 130 in the first 250 pages? Like not one of my schematics made it
into print without at least 2 errors?

>misinformation, but it does have a chapter on converting the 13-509 to
>repeater service. Dunno if it's still in print, though.

>You might also check out the "220 Notes" publication that comes (came) out of
>Chicago. That had lots of articles on 13-509 mods.

The 509 is your basic 12 channel crystal controled CB radio redesigned
for 220mhz. The repeater mods basically entailed remanufacturing the
transmitter for continuous duty (bigger heat sink, basically) and
cleaning up the spectrum (replace all the bypass caps, basically). The
RX local oscillator was spurry, causing multiple channel receive.
Changing a few resistor values and better bypassing fixed that.

Ray Von Neumann K6PUW designed a receiver for 220 that was described in
the book. Unfortunately the 3 paragraphs that stated whose design it
was, and gave contact info for him didn't make it past the editor.
Ray's receiver was the absolute top performer of it's day and is still
in use at that repeater. The transmitter exciter was a totally
re-engineered 13-509 TX followed by a 75w amplifier.

A better choice for a TX is to locate a Motorola U43MSN Motran and
convert the transmitter (basically cut out 5 capacitors, change the
crystal to one cut for about 149mhz (223.xxx/3 * 2), and retune)
Midland xtals can be used to test with, but will drift excessivly.
Expect 15-18w - fan required. Use two - one will fail eventually. Have

some kind of a airflow switch or a thermal cutout. The Moto PA transistors are rather expensive these days.... and Motran - specific parts are NLA.

The Moto MSN RX can be converted, but requires serious work on the front end helicals. If you want to do it, first locate a Microflame torch, or some other oxygen-assisted propane torch with a pinpoint flame. Oxy-acetelene might be too hot, but you need a hot flame no bigger than 3/4" long and small in diameter. A standard propane torch is about 10x too large. Picture a flame about the size of a knitting needle, and just as controllable. You have to unsolder the helical resonators in the front end, modify them and resolder them back in. The wire is about 10 to 12 gague and soldered to a heavy metal casting. Then you modify the LO multiplier to triple from 70mhz instead of doubling, and change the crystal and retune. Optionally for peak performance you need a drill press: the ports between the helical resonator cavities are sized for highband and are too large. The simple solution is to drill and tap a 6-32 hole in the lid, and run a screw into the "window". Tune the RX with the screw flush with the bottom of the cover plate, then run each screw in s-l-o-w-l-y until the sensitivity peaks for that stage, then tighten a lock nut. Repeak everything 2 or 3 times. The additional work to reduce the size of the ports doesn't buy much - a good GasFET preamp gets you much more.

The absolute best commonly available receiver for 220 is a modified Moto HiBand MICOR. If you can find one, get one for 160-170mhz - you will have fewer parts to change in the multiplier chain.
I have a Word Perfect file on the entire mod - the basic info is out of Tennesse, as I remember... The front end section also needs the MicroFlame torch trick to do it right, but the helicals _can_ be modified in place if you are very^2 careful (the MSN front end was about 4x4" where the Micor is about 1.5" by 6" - the Micor front end is much easier to butcher). Again, for best performance a good preamp needs to be used.

If anybody is really interested, e-mail me.

I've written TAB and offered to redo the book with up-to-date info, including much more info on repeater controllers (including computerized repeater controllers), but TAB (now a division of McGraw-Hill, as I remember) is not interested.

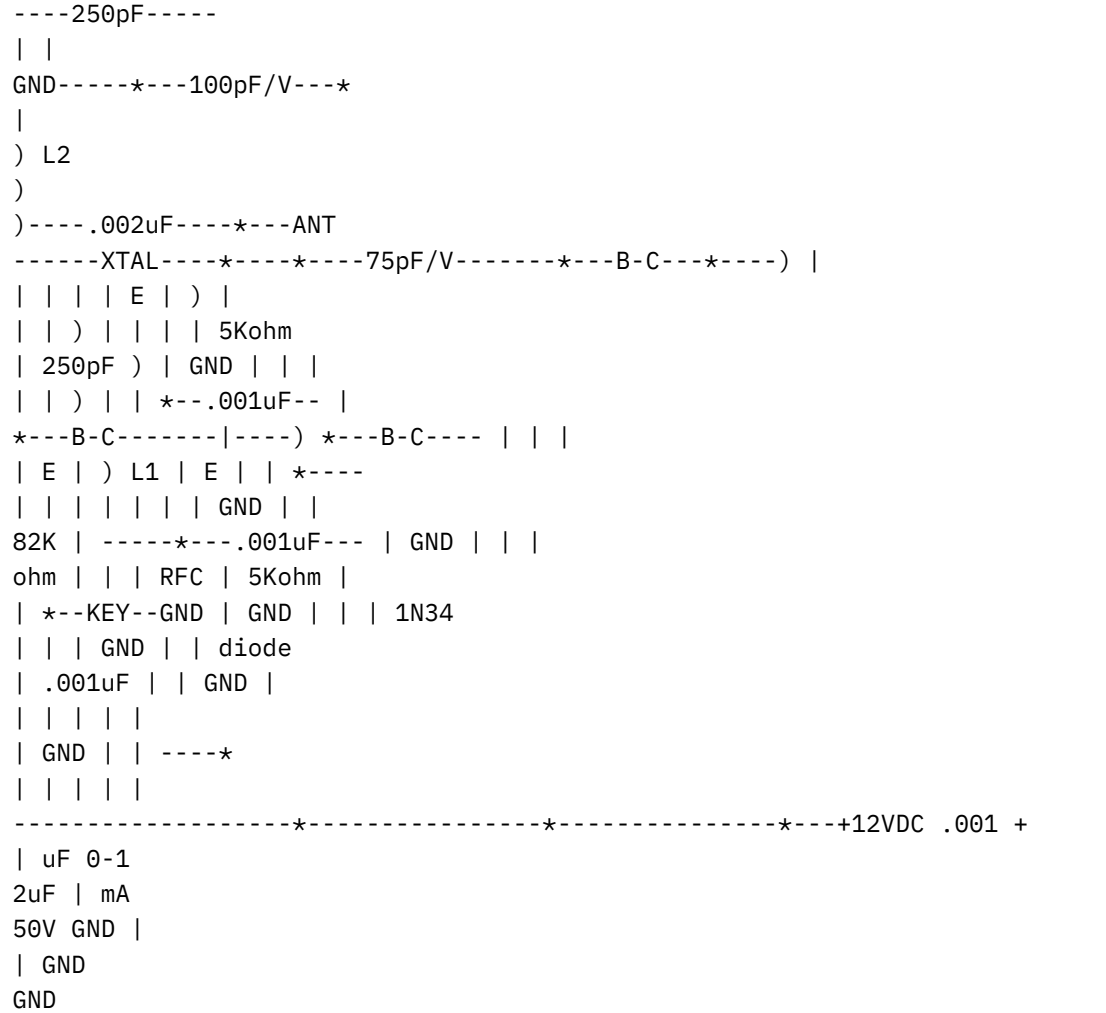
110. PROJECT 13: ANOTHER 80M TRANSMITTER

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-01-16 00:51:10 UTC
From: jherman@uhunix3.uhcc.Hawaii.Edu
Message-ID: <CJp6DB.CJ8@news.Hawaii.Edu>
Source record: 118908

Gang,
Here's another 80M xmtr; this one's supposed to be capable of 1-2 watts.
I got this out of a book called ``1000 Transistor Circuits'' or something
like that.



The 3 transistors are 2N2270. Two capacitors show: /V - means variable.
L1 is 30 turns on a B&W #3012 coil form, with a tap 10 turns from bottom.
L2 is 18 turns on a B&W #3015 coil form, tapped 3 and 7 turns from bottom.
Only numerical values were given for the capacitors so I've interpreted
this as ``whole number values are in pF and decimal values are in uF'',
except the 2uF 50V cap - that was specified.
The 1N34 diode's symbol should be oriented: \ /
\/

|

to meter

Now yank that 3579 kHz crystal out of your color TV set and have fun!

Source record: 118898

I have a Sealed lead-acid battery (Panasonic LCR12V17AP, 12v, 17Ah/20HR
, Constant voltage charge, Voltage regulation for cycle use 14.6v-15.0v,
for standby use 13.6V-13.8V, Inital current less then 6.8Amp). I wish
to use it as a means to both run higher amperage applications then my
2.5amp power supply (regulated @ 13.5V for 2.5amps load) will allow (the
modes would be SSB, packet, interrmitent FM voice) and also occasionlly for
emergancy power.

Is there a way that I can use my current power supply as a 'charger' to keep it
at full charge? How about if it gets drained? Anythings I shouldn't do? (Ie
I am sort of kicking around connecting the load, power supply and battery
in parrale but that doesn't quite sound right.. (Would the battery try to
chrage the supply?)
Thanks a lot for any help etc..N1MAM

You bet it will, and if the supply is the RS model, that'll trash the regulators. What you want to do is put a steering diode between the PS and the radio/battery. Use a low drop Shottky diode, or a selenium rectifier, to keep the voltage drop reasonable. Alternatively, you can use an ordinary silicon diode and modify the PS to put out 0.6 volts more than normal to compensate, should be 14.4 volts so the battery sees 13.8 volts float. If power to the PS fails, the diode will keep battery voltage from entering the supply and wrecking it.

Hi,
I live in a part of the world where toroids and other ferrite type inductors are difficult to come by. This makes it especially difficult for us to construct projects involving these components. Even trying to wind a balud is tough when one cannot
find the right components. In this situation, is there an alternative to using toroids? Could"we makeur own toroids? How do w��go
about ordering them and what kind of waiting period can we expect? Tks. Would appreciate any advise.

In addition to the blocking diode mentioned by another poster,
you also need a way to limit the current the battery will draw
from the supply when it is drained. All this was shown in QST
about a year ago.

A suitable current limiter is a couple of 1A 12V incandescant bulbs
in parrallel with each other and placed in series with the supply
output.

> effect, so whatever signal is strongest at the input to the limiter will
> dominate the output.

It is difficult to predict exactly the behaviour in presence of QRM,
mainly because the QRM can only be defined exactly in theory.
Surprising effects can be encountred in the real world.

> I don't know if any theoretical work has been done
> about the concepts of non-flat-bandpass pre-limiter filtering, or on
> nonlinear discriminators.

I known about few articles:

H.A. Ross, "The theory and design of Intermediate-Frequency
transformers for Frequency-Modulated Signals", A.W.A. Technical
Review, Vol. 6, No. 8, 1946.

P. Guettinger, "Die Verzerrung frequenzmodulierter Signale bei der
Bandfilteruebertragung", Brown Boveri Mitteilungen, Aug. 1946,
pp. 185.

> On the other hand, you might have a non-limiting path from the receiver

> you output mark; if both say space you output space; if they don't agree
> you output mark. Or you might decide which to believe by seeing which
> recently had the stronger signal.

Usualy the output of both detectors is subtracted immediatly, then
passed trough a low-pass filter before the logic operations mentioned
above are performed.

> TUs of both kinds have been built, or TUs where the limiter can be switched

That is exactly the most interesting case: to copy or not in marginal
situations.

> I did some experimenting years ago with positive feedback around the

> it did seem qualitatively that the feedback helped.

This is very interesting. Do you remember the 6DT6 tube ? This effect
is usually encountred with typical circuits associated with this tube.

Message-ID: <2hdjvu$hr0@wega.rz.uni-ulm.de>
Source record: 118909

Hello Netlanders,
I am looking for an IC which allows decoding of the 5-tone sequential pager codes which are particularly popular over here in Europe with public safety agencies, but I have heard them in the US as well. My two pagers are made by Motorola, anyway.

The project behind it is an alarm repeater for the mountain rescue group I work with.

Thanks in advance!

Best regards,
Hermann

>> 73 de 9VG (Singapore, South East Asia) Daniel

Daniel,

On scrounging,

You might try to use ferrite rods (sticks) which can always
be found in old, junk AM radios. These ferrite alternatives
will still have the property of reducing the required number
of turns to make a particular inductance.

Unfortunately, the rods will not have the self-shielding
property that the toroids have. This may be why most rod-type
IF transformers are inside an aluminum shield box.

Another problem is that ferrite materials are usually made
in several different "flavors" for different frequency ranges.
Thus, the "junk" AM rods may not work for higher frequency
(UHF/VHF) applications.

But it is worth a try while you are waiting for the slow boat
to arrive with your purchases.

AHH HAA ... Just had a great idea. Go find some dead switching
power supplies (in any PC, terminal, or disk drive box). Each
will have several toroidal inductors! Likewise, some modern,
high-end computer cables (crt, disk, keyboard) will have a pair
of toroidal inductors inside the cable's plastic skin near each
end of the cable. These toroids may be split in half. Don't
buy new ones, just try to find dead ones.

Good luck,

Chase Cotton

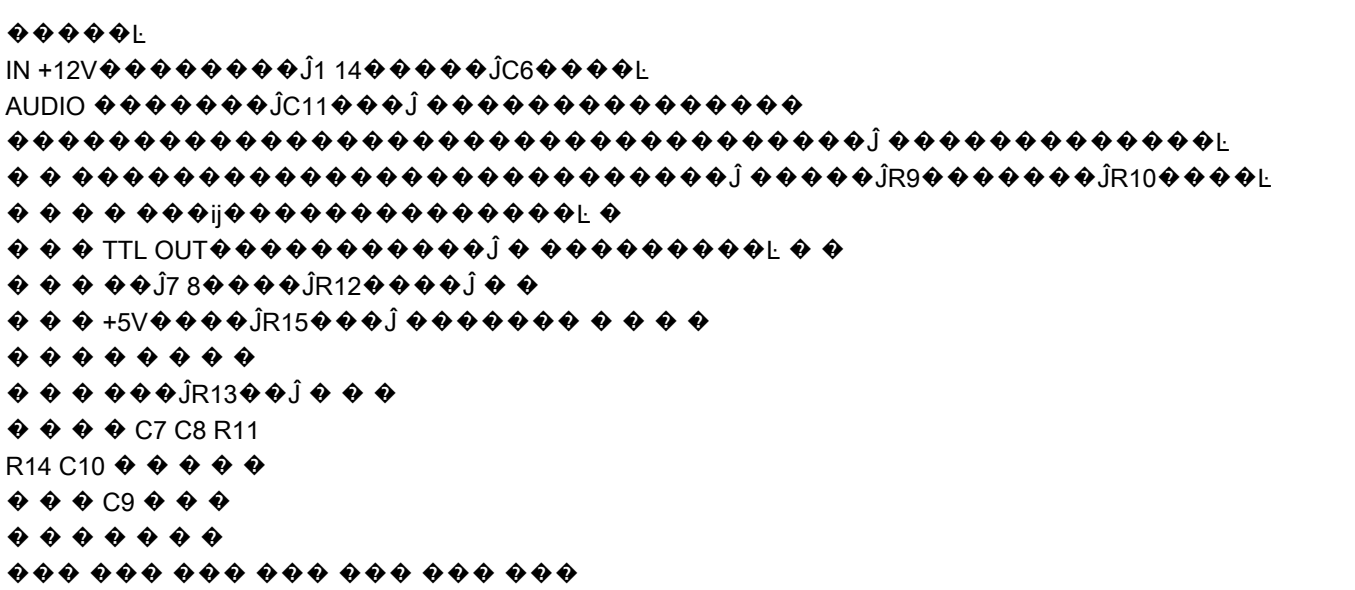
Can anyone send me any circuit for RTTY decoding based on the XR2211? Please
include as much info on the circuit as
possible, especially calculations for frequencies if possible. Tks.

DEMODULATOR USING XR-2211



R9 = 220K
R10= 15K NOTES: PINS 10 AND 11 DO NOT CONNECT
R11= 20K R11 IS MULTITURN POT
R12= 100K C6 MUST BE STABLE CAPACITOR
R13= 470K C9 IS FOR 110 ASCII/BAUDOT OR LESS
R14= 470K I SWITCH TWO CAPS AT C9 FOR LOW SPEED AND HIGH
R15= 10K SPEED USING .047 AND .0047(HIGH) 300 ASCII/BAUDOT

C6 = .022 ADJUSTMENT:
C7 = .0047 POWER TO PIN 1, ADJUST R11 FOR CLEAN COPY
C8 = .1 (I USE A STRING OF *U FOR ADJUSTMENT AT 110 ASCII)
C9 = .047
C10= .05
C11= .1

THE XR2211 WILL BLOW IF MORE THAT 2V PEAK AUDIO IS APPLIED.

160-190 khz is available with power input of 1 watt or less, *AND*

combined antenna/feedline length of 50 feet. The power limitation is
not nearly as bad as the 50 foot rule: it is very hard to get much
efficiency with an impedance of .1 ohm!

NDBs that operate 200-400 khz with 50 watts get about 20% efficiency
from a fifty foot tall by 150 foot long flat-top, with a full
number radial ground-system!

That was my experience. Years ago, when I was active on RTTY, I used a commercial demodulator that had both modes. Despite the enthusiastic claims of much-improved performance in AM detection mode, I found the advantages to be minimal to non-existant on typical on-the-air signals.

I'm looking for a 10.7 Mhz IF bandpass filter with a bandwidth greater
than 30Khz, preferably 50Khz for rxing WEFAX NOAA APT satellite signals.
Any ideas on where I could find such a beast. A complete radio could
also be
considered.

Thanks, Dino, VE2DM ;

I don't know of any IC that does this, but Communications Specialists has a line of paging and tone encoder/decoders that *I think* includes a 5-tone decoder. They are in Orange, CA at 1-714-998-3021, fax 1-714-974-3420.

>However, it is not obvious to me that threshold effect is relevant to FSK
>reception.

>Rick Karlquist N6RK

Of course it is relevant. You are never really transmitting discontinuous
frequency (bandpass, .etc) and in the case of the PLL demods, you will reach
a point where cycle slippage begins to kill you. ANYTHING you do to depress
the likelihood of cycle slippage in a PLL demod will be a major win. I
have written FM (FSK) discriminators based on a fully nonlinear model for
the phase locked loop (rather than the usual linearizing assumptions). The
problem becomes seriously nonlinear when you are in the transient region
just before coming into lock or just after falling out. If you make
use of this area with a nonlinear filtering scheme, you can significantly
depress the threshold. The papers you cite are indeed interesting. Thanks.

>rect. current, 800V rev. voltage, and 1.2V fwd. voltage. Will these work
>for this application? What significance does the fwd. voltage have?

This would not be the best choice. The forward voltage drop of 1.2 is excessive. I'd tend to use a diode with about a 10 amp rating and a forward drop of 0.2 volts (Shottky or germanium) for this application. The forward drop of a diode is essentially constant regardless of current draw, so if your supply put out 13.8 volts, you'd only get 12.6 volts on the other side of the diode. And the diode will dissipate the power represented by the forward drop times the current, so at 2.5 amps you'd need to heat sink the diode for a 3 watt dissipation. That's not bad, but a diode the size of a 1/4 watt resistor would tend to run pretty hot dissipating 3 watts. Thus the recommendation for a higher current rated diode because they normally come in packages designed to dissipate more power safely.

>Finally (please excuse my ignorance) I assume that you would connect the
>cathode to the battery, and the anode to the P.S., and give them a common
>ground.

Yes. Here's some ASCII art(?).

```
diode
PS+ ---->|--x----radio+
|
(L)
|
+Bat
-Bat
PS- --------|----radio-
```

L is an auto tail lamp for current limiting if the battery is dead. Note, if the PS has internal current limiting, you can disregard the lamp. You can also put a switch to short out the bulb for times when you want to run straight off the battery. That'll save the power lost in the lamp. For a low power radio, the lamp can be left in place with minimal loss.

Finally, a semi-unrelated question: I have a 12 volt, 5ah gel
>cell that I would like to use for this, but the fully charged terminal
>voltage is only 11V. How do I restore it to full capacity? (I know I've
>seen this thread before, but unfortunately, I didn't pay much attention.)

>Thanks in advance for any replies.

You can't. You have a shorted cell. Discard the battery.

Source record: 118826

SB-039

Alternator Whine, TR-7600/7625 7-9-79

In some mobile installations, alternator whine may be heard during transmit. External B+ filtering does not have sufficient effect.

In some instances, using the cigarette lighter will cause this problem. Running off the fuse block, and even directly from the battery may still not eliminate the noise.

First, check power line routing in the engine compartment. It should be kept clear of all secondary HV harness wiring, and clear of the alternator, regulator, and ignition primary circuits. Careful routing should reduce or eliminate noise coming in through the power line.

Check for clean ground connections at the antenna and radio.
Check for clean and tight battery connections.

If all of these measures fail, replace L22 on the VCO unit X50-1580-10 from the original green coil, to either an orange or black coil. No adjustments should be necessary.

Old part number L40-1021-03 1mH
New part number L40-1021-43 1mH

I realize that this in not a forum in which the advertisement of houses for sale is a generally accepted practice. However, this particular house would be ideal for those who have always wanted a tower to put an antenna on. The tower is a 51' three-section hand-cranked unit. It is mounted on an approx. 6'x3' slab which is as much as 6' deep directly under the tower. It was installed with all the necessary permits. The house is being sold by my parents who have just retired and are moving to the Sierras. I have included the information from the realtor's flyer below:

Unique Home situated on an Extra-Large Corner Lot in the "North Gate" area of Fremont. It's conveniently located within walking distance to schools, shopping, an AC Transit Bus Stop, and just minutes away from I-880, I-84, the Dumbarton Bridge, and B.A.R.T. for the commuter in the family.

Features...
* 4 Bedrooms (1 Bedroom currently being used as a Photo Darkroom)
* Tiled Entry Foyer
* Window Coverings
* Family Room w/ Chicago Brick Fireplace
* Interior Painted Approx. 5 years ago, some areas within the last year.
* Kitchen Includes: Built-In Range/Oven w/New Range Hood, Dishwasher, Tiled Counter Tops, and Dining Area
* 2-Car Garage w/ Auto Door Opener, Some Storage Cabinets & Shelves
* 2 Baths w/ New Sinks, Commodes, Shower Tile, & Lino Floor Covering
* Hardwood Floors Throughout with Some W/W Carpeting & Linoleum.
* Formal Living Room
* Composition Roof 3 Years New
* Extra Large Lot w/ Auto Timed Sprinklers & Drip Water System in both the Front & Back Yards
* Backyard has Patio, Fruit Trees, a Storage Shed and 51' Ham Radio Tower
** Approx. 1504 Sq. Ft. of Living Area **

Asking $219,950

I use a Cobra Scanner SR-900 that I use for ATP. By removing the 455KHz filter and replacing it with a 10 nF cap. you can get about 30-50 KHz band-with. You then tune the 455 KHz demod transformer for best reception. You can also add a resistor in parallel with the demod coil to widen the S-curve. The limit of the receiver is the crystal filter at 10.7 MHz. With a good ATP signal it will give a good result.

144. Amateur predicts LA quake (ELF)

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-01-19 04:53:20 UTC
From: btbg1194@uxa.cso.uiuc.edu
Message-ID: <2hiec0$dve@vixen.cso.uiuc.edu>
Source record: 118833
Cross-posted to: uiuc.org.synton,rec.radio.amateur.homebrew,rec.radio.amateur.antenna

A while back when I was doing some casual research on digitizing systems
and loop antennas for ELF field detection (60 Hz & under), I ran
across a guy in an Internet newsgroup who was an amateur studying
natural low frequency electromagnetic field patterns in relation to
earthquake prediction. I had a long file from him about the
techniques, but I cannot find it. I don't remember if this person
is a ham, but I do think that he was from the Kentucky/Tennessee area.

Here is another of his ilk, who might just become famous:

(Associate Press, Champaign-Urbana News-Gazette, January 18, 1994)

Amateur had sounded alarm over the weekend

SAN FRANCISCO (AP) -- An amateur who studies radio signals had
warned over the weekend that an earthquake capable of "devastating"
damage would hit California within three days.
Jack Coles, a former stereo salesman with no college degree,
operates the Early Warning EarthQuake Detection network out of his
home in San Jose, occasionally faxing his warnings to the media.
The fax he issued Saturday said he had received reports of "increased
radio signals, magnetic anomalies and many cases of electrical problems".
He warned that the results could mean a quake measuring more than 6
on the Richter scale.
The quake that hit before daybreak Monday in Southern California
measured 6.6.
"I had no idea the quake would roll the way it did," Coles said
Monday night. "I didn't think it would be this bad and last as long
as it did."

Hello all:

I just finished my kit last night. So far no QSO's under my belt,
but that will be taken care of soon! 8-)

My question is on the two adjustiable coils on the front end of the
reciever. What are they for? Are they for adjusting the cut off
frequency of the High pass filter? If so how do you adjust them? I
scowered the doc and assembly manual but could not find anything. Also
how does one accurately adjust the quaderature coil? Just for good
sound doesn't sound good enough to me... (I have this insaine desire to
use meters for EVERYTING... after all nothing is adjusted till a 'scope
sees it right!)

Any how, this kit was lots (make that a long time) of fun to
assemble, and well worth it. No if I can just figure out an antenna...

: me through a few years.

: What's your favorite PCB layout program?

I use Circad by Holophase Inc. It runs on any IBM PC with some kind of
graphics display (EGA or above strongly recommended.) It is written
in machine language so even a slow PC-AT/286 gives acceptable performance.
The demo version is free, the Radio Amateur version (identical to the
$1000 commercial version) is $300, as I recall. The demo version works
fine, but does limit the maximum PCB size.

The program does both schematics and PC layouts, with netlist checking
between the two. Output formats include Gerber photoplotter,
HPGL (pen plotters), PCL (Laserjet printers), and a bunch of others.
I find the program very powerful and easy to use.

According to my experience, the best way is to use an alternating sequence
of limiters and band-pass filters. The limiting quality (i.e. the threshold)
of each limiting stage is only on secondary significance. The important
fact is the alternating sequence. Of course, this is simpler to do on the
IF level.

According to my experience, the best way is to use a sequence

Hi;
I can testify to the existence of the article that you mentioned.
I believe that the title of the article made reference to, "whistlers."
The author described the phenomenon, along with, "morning sounds."
The author presented a receiver circuit and an account of the signals
he had received. The author hadn't anticipated receiving Navy VLF signals,
but the Navy was very friendly and sent the author some information that
was included in the article.

Faily recently I saw a well written technical article on whistlers.
I'm not sure, might have been in QST. Apparently lightning strikes have
their emitted radio energy (I'm not clear here...) ducted somehow by the
Earth's ionoshere....

I did locate all the parts to build the receiver but apolagize, did
not have the opportunity to build it. I recall that the design was fairly
simple. Like you said, a couple of op-amp stages and a power transisitor,
transformer combination to power a good size speaker. I have two places where
I store magazines, so it may be a while before I can check both.

I recall that Heathkit used to sell a VLF converter. The idea was that
the converter would receive VLF, upconvert the signal to the HF band, and
then you could use your HF rig as the tuner. Maybe consider asking if anyone
could sell you one of these VLF converter units used?

If you have a chance, locate the latest IEEE antennas and propagation
magazine. Try a good library. The historian has a bit on old radio techniques.
Apparently VLF was, "the thing" in those days. The author identifies the
major current Navy transmitter stations still in use. In Japan a 38KW Poulsen
Arc Set transmitter is apparently in use.

A few months back, QST had an article on VLF stations, licensing and
such. Apparently the FCC does not require licensing for VLF transmitters,
but nevertheless has strict rules on the configurations of such transmitters.
The author was inviting readers to join a group he called, "lowfers." Heck,
try anything once?

Hello. I have just read the Feb. issue of QST and found Measure's article on "The Perfect Amplifier" to be very informative. I am planning to implement his circuit for QSK and bias switching.

I'd like to hear from others who have successfully implemented homebrew QSK circuits in their RF amplifiers - whether they are retrofits of commercial units, or additions to a homebrew amp. Your experience and relections would be greatly appreciared. I'm most interested in how to set the timeing of the driver, amplifier and bias switching relays to prevent hot-switching.

Thanx for reading this and I'm looking forward to your response.

I implemented his TR circuit in a Henry K2000 amplifier. The amplifier used
a massive open framed dpdt relay that made the sound of a slamming door
everytime it was activated. Needless to say, it was slooow. I replaced
it with a Jennings vacuum relay (not the one he recommends but another one)
for output and a rf reed relay (obtained from Surplus Sales of Nebrasks)
for the input. I had to fool around with the circuit a bit:
- put in a voltage doubler on a 15v ac circuit to get about 42v dc
for the 26v relay (fed thru a current limiting resistor)
- re-wired the control circuits to work with the new tr relays
I tested it using a dual channel o'scope and it looked fine. Seemed
fine on the air too.

I am currently working on a medical amp with two 3-500Z. I plan to
follow Rich's circuits.

BTW, I highly recommend reading his earlier articles, getting in
touch with him and getting kits for mods from him. For a small
photo copying charge, he will send you lots more details about his mods.

Best of luck and cu on the bands,

: I'd like to hear from others who have successfully implemented homebrew QSK
: circuits in their RF amplifiers

I haven't done it on a KW amp, but have successfully done it on a 100 watt tube transmitter (Drake T4XB). The trick is to connect a SMALL capacitor to the top of the output tank circuit (on the output side of the tube plate coupling cap). The other end of the small cap is clamped to ground with a pair of diodes. The gate of a FET (RF MOSFET or JFET should work) is connected to the junction of diodes/capacitor. The FET operates as an amplifier to bring the signal level back up to feed to the receiver. I added a bipolar emitter-follower after the FET to get a lower impedance to drive the 50-ohm receiver input.

You can connect the diodes back-to-back to ground, but this might cause some IMD overload on receive, so I biased the center point up to half the FET supply voltage (which made a nice bias voltage for the FET gate anyway), and clamped the two diodes to ground and supply respectively.

The big tradeoff is this: The bigger the small capacitor, the more receive signal gets through and the better the receive sensitivity. But the bigger the cap, the higher the RF current through the diodes on transmit. I selected the cap to give about 1 Amp of RF key-down on 10 meters. (That's 1/2 amp through each diode.) The 1N4148 switching diodes I used seemed happy with this. Note that that half of that amp will be dumped through the top clamp diode into the positive FET supply. I used a shunt regulator rated at >0.5A to sink the current.

Bottom line: it works great. The QSK circuit gain is slightly greater than unity on receive, but it does seem to degrade noise figure slightly on 10 meters. If I need to hear a very weak signal on 10, I just let the T4XB's T/R relay drop out and operate in non-QSK mode.

I also had to make some other slight mod's to the transmitter to bias off the output tubes in the key up condition and to rewire the receiver input line that comes from the T/R relay. I have the schematic around somewhere -- if anyone sends me an SASE, I'll send a copy.

164. Re: Portable 2m Antenna for Mountaineering???

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-01-21 14:47:21 UTC
From: zlau@arrl.org
Message-ID: <1994Jan21.144721.5694@arrl.org>
Source record: 118856
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

A simple dipole can be a surprisingly good portable antenna
if used intelligently. By adjusting the location and polarization,
you can often come close to the gain of a small beam. Since
a 2 meter dipole is small and balanced, it usually isn't too
difficult to hold it in the optimum position.

However, a beam makes more sense for setting up long distance
(200 to 500 mile) microwave contacts, where two or more antennas
have to be kept in alignment.

I've found that Cushcraft antennas can be folded into slender poles
if you loosen the elements, rotate them 90 degrees, and retighten
them. Unfortunately, you can lose hardware getting up the mountain.
Of course, many of these antennas can sacrifice an interior director
without losing any gain, so perhaps this isn't much of a worry.

My latest mountaintop antennas are built like the K1FO antennas with
retaining rings. The antennas will not fold up, but littering
the mountain with stainless steel hardware is less of a problem.

There was another Baghdady paper circa 1958 that said you should have alternating limiters and bandpass filters in order to optimize capture ratio for analog FM. The theory was that the limiter had the effect of converting a lot of the beat note interference to frequencies beyond the IF passband. These were removed with a subsequent filter, but the filter reintroduced AM to the signal, which is why another limiter was needed, etc.

From article entitled "Universal Digital Frequency Readout", QST January 1980.

Built and tested (2) PCB set. The main logic board is 5"W x 3"D and the dis-
board is 4 5/8" W x 2 1/8" H. Not included is 5V power supply and enclose.

Features (4) .3"H 7 segment LED's. For example, 14.285500 Mhz will be displayed
as 285.5. The counter has selectable presets (via dip switches) on the decimal
counters and it can count in either the up or down direction. These features
are allow the unit to be used on any receiver / transmitter mixing scheme
(i.e. The VFO frequency is counted and the frequency of the IF, offsets etc.
are added or substracted).

Ideal for updateing your Drake, Tentec etc.or adding to your homebrew project.

Price is $45.00 + shipping.

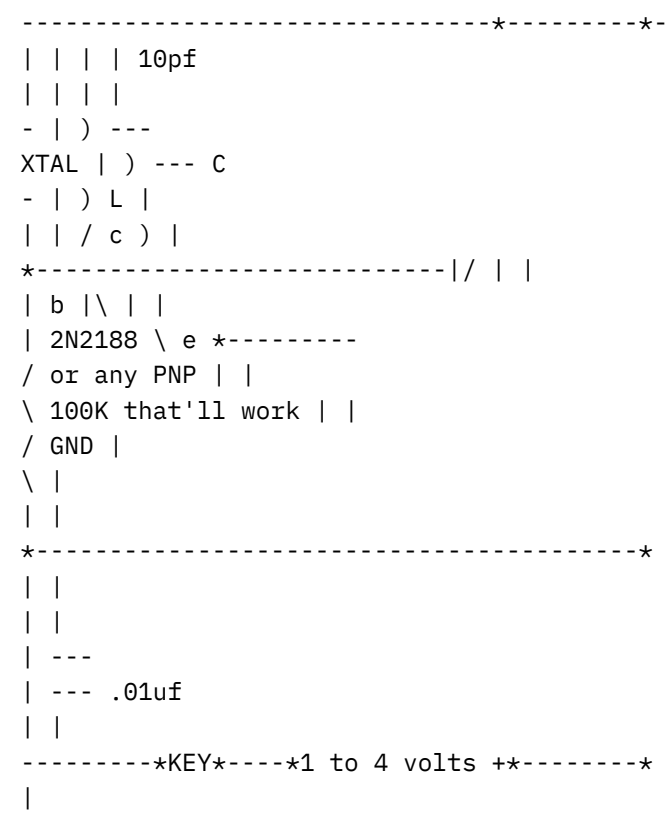
168. PROJECT 14: THE WORLD'S SMALLEST TRANSMITTER

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-01-22 05:47:24 UTC
From: jherman@uhunix3.uhcc.Hawaii.Edu
Message-ID: <CK0o31.54n@news.Hawaii.Edu>
Source record: 118858

Gang,
If there was a contest to come up with a xmtr containing as few
parts as possible, this would be the winner: 10 parts if you include
the key, battery, and antenna!
In the CODE/NO-CODE debate on r.r.a.policy some pro-coders will
mention the simplicity of CW xmtrs as opposed to those of other modes;
this circuit really drives that point home (that's why I'm posting this
on .policy)
On r.r.a.misc we've heard talk about how costly ham gear is today - all
this rig will cost you is the effort to find an old color TV chassis -
that's the parts source for all my QRP transmitters (and this is why I'm
also posting this on .misc).
Normally I post these xmtrs only on r.r.a.homebrew and on the QRP
mailgroup; so if you've missed the first dozen xmtr circuits email me
and I'll send them off to you.
I built this for 80M only because I've got so many 3579 kHz crystals
from old TV sets, but this can be used on any HF band - just choose
L and C to resonant at the crystal frequency.
For peace of mind you might want to add a bandpass filter to the
output.



|
GND

Again, choose L&C to resonant at the desired frequency; one of the two should be adjustable. I got both from the chromatic board of a TV - both were sitting next to the 3579 kc xtal; easy, huh? I didn't use a 2N2188 transistor; rather, I used a x-sistor right off the video board (of the TV).
So, don't you dare buy one component for this - just dig through your junk box (or your neighbor's trash for an old TV). With a good antenna (those are the magic words in QRP work) this little peanut-whistle will provide hours of pleasurable QSO's.
Oh, 3579 kc has become a national QRP frequency due to the easy availability of these crystals.

.... .- ...- . ..-. ..- -.

72,
Jeff NH6IL

Hello fellow netters. I have a question. In a pre 1990 magazine which I think was an Electronics Now catalog, there was an article written about a Frequency that is open as a freeband. Included in the article was a parts list and schematic for making your own xmitter and receiver so that you could contact people on CW or Voice with a range of about 300 miles. It was QRP for sure but does anyone know what issue that was or if I even saw it in that particular magazine? Thanks for any help. You can reply here or at kb0dmu@k0kkv. Thanks

>In a few word when I must use it ?

Hot-carrier, or schottky, diodes use a metal-semiconductor junction rather than a junction made of P- and N-type semiconductors. One of their distinguishing features is a lower forward voltage drop than silicon PN junction diodes. Depending on the metal used, the forward drop will typically be from around 0.3 to 0.5 volts at low current, vs 0.6-0.7 for PN junction diodes. A second important characteristic is lack of charge storage. When a PN junction diode is forward-biased, charge is stored in the junction area. The charge remains after the forward bias is removed. This causes the diode to stay on for a period of time after bias is removed. The lack of storage is important in vhf/uhf/microwave mixer applications, and in some switching power supply applications. The lower forward drop enhances detector sensitivity and permits making mixers with lower LO power being required than if PN junction diodes were used. Lower forward drop also leads to better efficiency in low-voltage power supplies.

On the down side, schottkys are more expensive and somewhat more fragile than PN junction diodes. They also have much greater leakage when reverse-biased, a property which sometimes negates the advantage of lower forward drop in power supply applications. The forward characteristic isn't as sharp as for PN junction diodes, so at high currents the forward drop can equal or exceed that of a junction diode.

In a few words, use small-signal schottky diodes for vhf/uhf/microwave detector and mixer applications.

You can find more information about Hot-carrier diodes in the ARRL Handbook. It's on p. 4-6 in the 1992 edition.

I believe it's just another name for a Schottky diode.

In a normal silicon diode, the diode junction is formed by the contact between two oppositely-doped (N and P) pieces of silicon. In a Schottky diode, the junction is formed between one piece of silicon and a metal contact.

Since the contact junction can be made very small, the junction capacitance is also small. The main advantage of Schottkys is that they work at very high (microwave) frequencies. They also have lower forward-conduction voltage than junction diodes, so they are sometimes used as power rectifiers for that reason.

As the subject line says, I want a tunable receiver that will pick up Air Bands (108-137 Mhz). I don't need anything fancy, but I don't have much to go on. What would this entail, it can be rough but needs to be cheaper than buying a $100 scanner with the same capabilities (except lot's fancier). I had (as a kid) a radio shack kit that built an AM receiver, is that pretty close to what I have to do to pick up these higher freq's? I figure some of you guy's would know. If you know of a book that would tell me what I need, that would work fine. thanks in advance....

If the IF is an integer MHz (for example, 9 MHz), then you could tap into
the output of the local oscillator, and ignore the MHz digits on the
counter. That way, the counter would work on receive, too.

>from old TV sets, but this can be used on any HF band - just choose
>L and C to resonant at the crystal frequency.

Try using a 4049 or 74C04; use one inverter as a crystal osc (two caps + crystal) and the other five in parallel as a buffer. Use a small cap to couple the antenna, maybe 100pF. It'll run off 3-15V. Lessee.. xtal+74C04+caps+battery+key+antenna = 8 parts.

The 74C04 was invented in something like 1973.

> For peace of mind you might want to add a bandpass filter to the
>output.

or maybe a lowpass filter; that adds at least three more components. The 74C04 approach would really benefit from an LPF, too.

Oh, is this a CW issue? :-)

Sorry for the innocent question BUT :

could anybody explain me what a "hot carrier diode" is and what is
the difference using it and another kind of diode ?
In a few word when I must use it ?

Thanks to everybody

Roberto

Howdy,
I believe that a hot-carrier diode is the same as a schottky diode. These
diodes are doped such that they have a slightly lower Von, and do not
saturate, so that they will transition to off more quickly when Vfb goes
below the threshold.

Cheers,
Carl

Depending on your taste, here's a pretty simple solution. Get yourself one of those cheap made in the Far East FM broadcast radios. Now when you open these sets you will normally see one or two small coils of enamel coated wire, especially near the tuning capacitor. As you move your finger near one of these coils, you will find that the radio detunes. That coil is the mixer oscillator coil. What you need to do now is to gently pry the windings apart so that the spacing is greater now. Step two is to indentify the trimmers behind the big tuning capacitor. Usually such small radios are AM/FM. Behind the tuning capacitor you usually find 4 trimmers. 2 are related to AM and 1 is for the FM coarse tuning and another for the telescopic antenna matching. I leave it to you to experiment. The coarse tuning will have the effect of changing the tuning range, you should turn this so that both the plates are visible to you. The antenna trimmer is for you to adjust for best reception. What you can do is tune to any FM station, see which trimmer detunes it, that is probably the coarse tuning. Finally, look for a light blue IF transformer can. This is sometimes white but it is the discriminator transformer. Turn this slowly until the white noise (the hissing) becomes loudest. This is necessary so that the AM reception is clearer since most FM also has some AM ability. Now tune to some station in about 124 mHz (you go figure that out yourself). When the transmission comes on. Tune the antenna for best reception. There is ANOTHER coil on board which is normally close to a bunch of capacitor and one transistor. This is the RF amplifier section. You can also stretch the coil a little to get better gain at Air-band.

There you go. A cheap ($5 or so) but working Air-band monitor.
Of course you don't get digital display or memory scanning .... but what do you expect :)

Have fun. 73 de 9VG Daniel

>
>Does a typical center-tapped full wave rectifier limit me to 24V at 12 Amps?
>Also, is there a way of getting 24V at 24 Amps out of these things!?

I've faced this problem many times over the years. It seems that 24 and 48(CT) volt transformers are a lot more common than the 16 or 32(CT) volt transformers you want for a pass regulated 13.8 volt supply. The way I solve it is with a switching pre-regulator working on the primary side of the transformer. Chopping at 60 Hz isn't terribly efficient, but if you do a missing pulse design, switching at zero crossings and eliminating whole quarter cycles, you can get a good enough voltage at the filter capacitor to drive a normal series pass regulator without having excessive drop across it. You do need to maintain some load on the supply at all times or it becomes erratic. A heavy bleeder shunt can handle this. If you want better efficiency, you can use a shunt pre-regulator circuit before the final pass regulator.

To get 24 amps, just parallel two of the transformers (watch winding phasing).

Of course there is another alternative. Open up the transformer and remove enough turns on the secondary winding to get the voltage down to the desired value. That's easier said than done in many cases, and silicon is cheap, iron is expensive, so using the pre-regulator approach is a good way to deal with the problem.

Pete

While your transmitting, your SSB or CW modulation will cause the frequency counter display to bounce around. It will only be readable on steady carrier. This method (sample output) also does not allow you to read your receive frequency.

A better method is to connect a counter to your VFO. Now you will also be able to constantly read receive and transmit frequency. Your fluke counter is not very appropriate however.

Each radio has a band plan (i.e. the relationships between the mixing process and resultant VFO, BFO, IF frequencies). Unless your radio has a 0 IF frequency, as in the case of direct conversion, the counter used will need to take into account whether it needs to count up or down, and be able to count from a pre-determined off-set determined from your radio's band plan. However, there are commerically built dials taht do this, or you can build your own (refernce Jan 1980 QST for construction article). The counter featured here can count up or down in frequency and has pre-settable decade counters.

The measurement principle is simple: the frequency of the VFO is counted and the frequency of the IF is added or subtracted from the VFO count (depending on the equipment frequency mixing scheme).

There is also a way to use your standard counter. This would envolve building a mixer which would installed between your VFO and counter. The mixing scheme could be selected to off-set the IF frequency etc..

These are the ways that you can read your equipment frequency, however it probably was not the answer you were hopeing for.

Most likely you could wrap a few turns of wire around the feedline and
use that as a little antenna for the freq counter. Mine's sensitive
enough to read the freq. Does the triton have an low level RF output?
My FT-102 has a +- 1mW output that'll do just dandy.

Another alternative is to insert a low-voltage winding in series with
the primary to reduce the effective primary voltage. If there are two
24-volt windings on the same transformer, for example, just wire one
in series with the primary to reduce the primary voltage by about
20 volts. That will give you 20 volts on the other "24V" winding.

If you don't have a second winding, you can use a second transformer.
It doesn't need to be high-power since its secondary only needs to pass
the primary current of the main transformer. (Primary current =
slightly more than secondary current times [Vsecondary / Vprimary].)
You'll have to experiment to get the winding polarity correct, since
phasing is rarely marked.

>pre-filtering?

Normally, a preamp is unnecessary for the HF spectrum. The usual problem
is inadequate rejection of strong signals. However, if you've got an old
deaf receiver, like say a S-28, a preamp may help. You definitely want to
use a selective amplifier with good sharp tuned circuits. A triple ganged
circuit would be a good idea. Otherwise your preamp will operate in overload
most of the time.

> What are the advantages of designing one around bi-polar or mosfet?
>Can anyone contribute some tried and tested circuits for me to construct?

FETs would be the more popular choice. You can tap up on the selective
circuits for lighter loading, hence higher Q, with less problems with a
FET. The old MPF102 would work for this type of circuit, but it can
be driven rather easily into overload. A power VMOS FET like the VMP-4
may be a better choice. Run about 100 ma of standing current.

In looking through my collection of ARRL Handbooks, I don't find a
HF preamp until I go back to the 1962 edition. They have one using
a 6AK5 pentode. This should give you an idea of the apparent lack
of need for such circuits with more modern equipment.

If the problem is that you are using a small voltage probe antenna,
a FET configured as an emitter follower mounted directly on the
antenna may be used to transform the signal impedance down to
something more to the liking of the receiver and coax. Again run
enough standing current to avoid overload problems.

**** Here's another way. You can use pre-settable counters, and instead of presetting them to zero, you preset them to the two's complement of the IF frequency. That way, the count goes up from (negative-of-the-if-freq) through zero up to the actual frequency of interest. This assumes high-side injection of course.

If you have a unit with different schemes for transmit and receive, then you just arrange to preset the counter to one value for xmit, another for receive. The scheme could even be expanded with diodes for bandswitching.

195. ICF-2010: adding filter, mods? Help!

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-01-26 10:29:39 UTC
From: asirene@ntuvax.ntu.ac.sg
Message-ID: <1994Jan26.182939.1@ntuvax.ntu.ac.sg>
Source record: 118732
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Hi,

Can anyone tell me how to change the narrow and wide IF filter
inside the ICF-2010? What kinds of filter can I use? Can I use filters for
say the ICOM (FL-series) or Kenwood. 1) Will these work, 2) Will these fit?
I heard of the Kiwa filters for the 2010 too.

In general what kind of improvement can I expect out of using such
filters?

Can someone direct me to any sites where I can find out what kinds
of mods are available for the Sony ICF-2010/2001D? Tks.

I'm getting ready to put a dipole up and use ladderline to feed it. I'm going to need an antenna tuner so I can tune this wire across 160-10m.

I thought building a tuner would be a nice winter project. Do any of you have a favorite tuner project you would like to point me to?? My rig is an ICOM IC-740, 100 watts out.

Thanks for the help!

Bruce

: also not sure if I can locate crystals at 16.660Mhz and 16.600Mhz. Im trying
: to convert an FM pocket tranciever into a cordless phone unit. Any help will
: be greatly appreciated.

I order my crystals from either International Crystal Mfg. (ICM),
1-800-426-9825, or Jan Crystals, 1-800-526-9825 (just noticed the
similarity between those numbers, but I've talked to both outfits
recently on their 800 numbers). They will make crystals for any
frequency, holder style, etc that you need. They keep crystal data
for a lot of equipment, so you can sometimes just specify the unit
you need the crystal for. Other times, like the 200 kHz I needed
for an old R-390A receiver, you must specify the type of circuit, etc.
I once copied part of a schematic diagram and sent it in and let
their people determine the crystal load capacitance for me. They
both seem to be very accommodating people.
Obviously, I'm assuming you're located in the U.S.--not sure by your
posting.

There are a lot of antenna coupler designs, and some folks have favorites that they defend quite strongly, however, I've had good luck with the 'Ultimate Transmatch' design that can be found in older ARRL Amateur Radio Handbooks. Another design that is supposed to be good is the 'Series Parallel Capacitance (SPC)' that is shown in newer handbooks. I tried it and couldn't get it to do what I wanted, so went back to the 'Ultimate'. I haven't given up on the SPC, though, and have plans to try it again.

A preamp may be needed for upper bands if bands are quiet and antennas
not spectacular. A single tuned circut would cut out a mirror frequency
pretty well. Once I build a one-transistor preamplifier with one tuned
circuit, and it made a large difference on my SWAN 500.

>> What are the advantages of designing one around bi-polar or mosfet?

>may be a better choice. Run about 100 ma of standing current.

MOSFETs and FETS may have too low gain to drive the coax. Large-signal
properties of a RF amplifier are not terribly important, especially
with the tuned front. It is usually the mixer that is more susceptible to
overloading.
Once I used a linearized bipolar transistor in the traditional
configuration, linearized with a 50 Ohm (I am not sure of the exact value)
resistor in the emitter.The coax was connected to the collector, which was
fed by a 100-200 Ohm resistor. The current was about 20 mA.

>In looking through my collection of ARRL Handbooks, I don't find a
>HF preamp until I go back to the 1962 edition. They have one using
>a 6AK5 pentode. This should give you an idea of the apparent lack
>of need for such circuits with more modern equipment.

The problem of unproper gain distrubution in various stages is still a
problem. Look at smaller ICOMs, where you can hear plenty of noise from
the IF stages, particularily with a CW crystal filter in the first IF.
Intermods spoil the reception sometimes, but such a noise spoils it
much more often. Sometimes I would like to have more RF gain

in my IC-735 on 10-20m. Perhaps my antennas are not spectacular.

>If the problem is that you are using a small voltage probe antenna,
>a FET configured as an emitter follower mounted directly on the

I've used this S/W also; it is excellent. The documentation leaves something to be desired; nowhere is it stated that you can mirror text (strings) by selecting text for moving, then typing an 'x'. Small complaint for something that's free; I've used it for several boards already.

There has been some activity at around 150 kHz in Australia and
New Zealand. Circuit diagrams and construction notes has been
published in Amateur Radio, which is official WIA magazine. I don't
have any exact references at hand, but some articles has appeared
during 1993. You can get copies of this journal from WIA: Amateur Radio,
P.O.Box 300, Caulfield South, VIC 3162, Australia.

The only reference at hand is: Lloyd Butler (VK5BR, addr. 18 Ottawa Avenue,
Panorama, SA 5401, Australia) - A Bandwidth Limiting LF Up Converter
for Frequencies Around 200 kHz. Amateur Radio, December 1993, p. 4-7

In fact, this article contains references to: Butler - VLF-LF and the
Loop Aerial, (aerial is antenna here ...) Amateur Radio, Aug. 1990 and
John Adcock (VK3ACA) - The day we crossed the Tasman on Long Wave,
Amateur Radio, April 1993 (Crossing Tasman sea means contact to NZ)

I have faint idea about these US magazines. The LF articles were
quite good, but in this respect I can not help.

I hope this helps.

There was a series of articles about VHF - UHF crystal oscillators build around MMIC amplifiers (Mini-Circuit, Avantek and some Japanese ICs) in the RF Design (USA) journal about 1989 - 1992, most probably 1991. The main idea was to make the oscillator to work directly at 100 - 500 MHz. In some circuits, the author used special, low capasitance crystals.

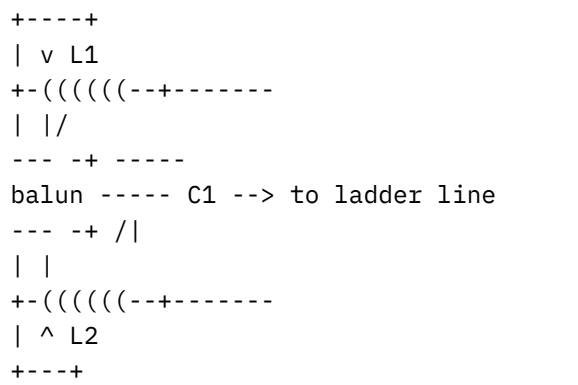
Richard Measures, AG6K, wrote an article in the Feb. 1990 QST about a balanced antenna tuner, made for just such an antenna system as you describe. The balun is at the input of the tuner (i.e., between the transmitter and the tuner). The tuner itself consists of two roller inductors for the series reactances and a variable capacitor for the shunt reactance.



The roller inductors are mechanically ganged by a belt and pulleys on the inductor shafts. The idea of a balanced tuner feeding a balanced transmission line to a balanced antenna is appealing...

Actually, the problem with modern Mosfets is in taming the *excess*
gain they possess. Many have 15-20 db of gain well into the gigahertz
region, and gain suffers a 3 db increase for every octave frequency
decrease. So at HF they're generally hotter than firecrackers. You
don't want more than 10-15 db of gain in a preamp or you'll definitely
overdrive most HF rigs into distortion and intermod. It's also a fact
of life today that strong signal handling has become the major problem
at HF. Using either very selective networks, or amplifiers with strong
signal handling characteristics, or both, is a must. Most modern receivers

use a DBM first mixer with +8 dbm or greater LO injection, so mixers aren't the weak link anymore.

Indeed. With my IC-735, atmospheric noise dominates the quiet channel. Of course channels are rarely quiet. A good antenna is always a must for proper performance.

They can be, if not properly designed. But this is more a problem with low impedance bipolar circuits than with FETS. Adding additional degenerative feedback in the emitter circuit will tame this problem. The FET will have more gain than you want anyway, so this is a viable solution.

Gary is probably right but then if you look in the MFJ catalog I
am sure you will find one or two active antennas, which are quite expensive
when you consider the number of components involved. Thus in case of the
lack of a good antenna, active antennas/pre-amps still help.

> Actually, I recommend this circuit... I built it when I was a kid and

> --scott

However, a valved pre-amp was not quite what I had in mind :) I was
thinking more along the lines of the dual-gated mosfets or bi-polar types
for broadband amplification as well as for narrow band. :)

Hi,

Does anyone know if I can use the SSB filters for ICOM or for Kenwood in other radios or in my own IF strip? I am thinking of use for SSB/RTTY/CW. The reason I ask is because the Kiwa filters I want are not available locally but the ICOM filters are. Does anyone who have access to both know?

I am looking to put the ICOM narrow filters (2.4 kHz) into my SONY ICF-2010/2001D. Does anyone have any comments about doing this?

The book you may be looking for is called "Care and feeding of
POWER GRID TUBES" by Varian EIMAC. The copyright is 1967 and I
have a copy of the fourth printing which was in 1982. The Library of
Congress number is 67-30070. The book has about 160 pages and
covers just about everything a designer needs to know about
power tubes. The price printed on the cover is $5.95 in the US.
I got my copy for free from Varian EIMAC Division, 301 Industrial
Way, San Carlos, CA 94070.

I have no idea if it is still in print or available but I hope this
lead helps.

221. Crazy VFO

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-01-28 08:13:01 UTC
From: robertov@flash.ATC.Olivetti.Com
Message-ID: <2iahed$k2u@olivea.ATC.Olivetti.Com>
Source record: 118757

I cannot exlplain this to myself :

I build a VFO that is very similar to the VFO of the
"Optimized QRP Transceiver" from Roy W. Lewallen
W7EL , the only difference is that it
is not for the same frequency because I have to use it in a
etherodyne transceiver born for fixed cristal oscillatorA
operations.

The Vfo was performing good , after warming up for 20 minutes
it was moving in a range of max 20 Hz.
The frequency from power-on increase of 90-100 Hz.

The operating frequencies are from 8050 to 8190 more or less.
Output 1.5 Volts pp over a 50 ohm load.
Now the problem is that if I put the vfo inside its metal box
to make it usable and connecting the box itself to the ground of the
vfo (as it should be) etc etc ...
In a few words putting it in its
final state then it starts to become instable increasing or decreasing
its frequency of more than 800 or more Hz and trying to drift also after
more than 1 hour from power-up.

The last info I used a copper board like one for pcb scraching out copper
for making the needed wiring leaving a lot of copper for the ground connections

I hope to have done a good desriptions of the item.

Also I took out from the box the VFO and it returned to original good
performance.

IT IS DRIVING ME CRAZY !!!!!!

Roberto

: to point me to?? My rig is an ICOM IC-740, 100 watts out.

: Thanks for the help!

There are a lot of antenna coupler designs, and some folks have
favorites that they defend quite strongly, however, I've had good
luck with the 'Ultimate Transmatch' design that can be found in
older ARRL Amateur Radio Handbooks. Another design that is
supposed to be good is the 'Series Parallel Capacitance (SPC)'
that is shown in newer handbooks. I tried it and couldn't get
it to do what I wanted, so went back to the 'Ultimate'. I
haven't given up on the SPC, though, and have plans to try it
again.

Mike, K0TER

I'll second Mike's comments on the "Ultimate". I built one in the seventies, as
did a friend. I tested mine in a configuration I expected to use and called it
good. My friend tested it at 100 Watts on 20 meters into a coathanger hanging
over the curtain rod. It CAUGHT THE CURTAINS ON FIRE! (but it did load...&->)

Cheers,
Carl

Yes it is, but be careful of C1. It has to float hot and most variable
capacitors have one side attached to the frame making it hard to maintain
balance. You can mount it on a sheet of plexiglass, and don't forget
an insulated tuning shaft. A capacitor that has both sets of plates
insulated from the capacitor frame is best, but they're harder to find.

Jeff Herman's post about the world's smallest transmitter seems to have stirred up considerable interest. Does anyone have a collection of simple receiver circuits that could be paired with Jeff's transmitters. I would like to build a QRP station but have been away from building things for some time.

Maybe we can renew interest in construction projects.

>
> The 74C04 was invented in something like 1973.
Try using a 28.322MHz oscillator (or a14 or 7 meg that I've
seen occasionally that are still in the Ham bands). Low-pass filter
this as well, and you need battery+key+oscillator+3xLPF components.
Note that these oscillators are usually not a 50% duty cycle, so a
bandpass filter would be better.
> > For peace of mind you might want to add a bandpass filter to the

> or maybe a lowpass filter; that adds at least three more components.
> The 74C04 approach would really benefit from an LPF, too.

Of course, taking that approach to extremes, use an Alinco
DJ580. It is all one 'piece', including the battery, key and antenna
;-)

I built mine for the 20m band and it puts out about 2vpp into a 50
ohm load. (after the buffer). An unrelated comment: did you
pick up the new buffer from the feedback column in Nov 1980 QST?

>IT IS DRIVING ME CRAZY !!!!!!

It would drive me crazy too. ;(

I think that there may be two things going on:
1. a long term problem such as heating that is contributing to

drift after an hour and
2. a short term problem that may be related to improper grounding/ground loops or not stiff enough connection between vfo and box. This could lead to:
- abrupt changes in parasitic capacitance and tuned frequency as components move about - not so micro micrphonics
- parasitics induced because of inductance from ground loops and parasitic capacitance. This may also explain the increased long term drift as the components get warmer.

>IT IS DRIVING ME CRAZY !!!!!!

Usually, I have found that "unexplainable" oscillator problems can
be traced to UHF oscillations. Many colpitts oscillators have a
capacitor from the base to ground. At UHF, the transistor becomes
a grounded base amplifier, and you know how easily those things
oscillate! Try putting a ferrite bead on the base lead of the transistor.

>Do any of you have a favorite tuner project you would like

"A *Balanced* Balanced Antenna Tuner", February 1990 QST, page 28. Or some variation on the idea of putting a 50 ohm balun on the INPUT of the tuner, not trying to use a balun in the output to the line.

The above is a balanced L network -- with the inductance split between the legs of the line, and the capacitance across the output. You then feed this with a current balun, like a large coil of coax, or the W2DU choke balun, or even a good broadband transformer.

Another variation on this idea is the QRP Transmatch for Balanced Lines found in my 1988 ARRL Handbook (maybe later editions too). He doesn't split the inductance, but does put the balun on the input, and keeps the matching network floating.

In any case, avoid putting a toroid balun on the output when yoy're going to feed a non resonant, reactive load such as a dipole used on all bands. They are not designed for this, despite their almost universal use in commercial tuners. Another QST article, I can't remember where, documents how badly they work under reactive loads.

I use two rotary inductors, a variable capacitor, and a coax balun consisting of about 30 feet RG58 on a five-inch PVC pipe. Works great -- solved a LOT of RF problems in the shack with a balanced open wire on most HF bands.

I have had a military surplus T368 VFO/multiplier for some time. I hooked it to my old Heath DX60 when I first got back on the air about 5 years ago, and it was a marvelous VFO -- far more stable than the mating HG10, and cost $35 from Fair Radio Sales at the time.

If you're not acquainted with the unit, it has a 1.5-3 MHz PTO, a mechanical digital readout, and doubler stages to cover 1.5-3, 3-6, 6-12, and 12-24 MHz (they say 12-20, but the dial reads to 24; probably reflects the ratings of the companion PA). It's built like a tank, and the tuned circuits in the multipliers track the PTO in typically elegant Collins fashion.

Lately I have been building up Rick Campbell's R2 receiver, and have had a 5 watt transmitter for some time, built while I was trying to see if Rick was going to provide kits! When it became apparent that he was barely able to keep up with circuit board requests, I made my own and went forward. Gradually, I realized that the old T368 would be a marvelous general-coverage VFO -- it's built like a tank, far more stable than I could ever construct.

Suggestions for transistorizing the PTO were made in Feb. 1989 QST Technical Correspondence. I adapted those ideas. so far, so good.

I was on my own on the multiplier stages. I chose to wire in JFET's, using the locally-available NTE312. One stage had a weird low-frequency oscillation, but I cured it with a series RC network. It worked! Then just broadband output stages to boost the power up for those hungry diode-ring mixers.

While I was at it, I added a tuning diode to the PTO for RIT and CW offset. I have two pots (found matching knobs at a local surplus house!) and a switch added to the front panel, and a transistor switching arrangement to select the correct pot when the transmitter is keyed. Works well with full QSK.

Does this trip anybody's trigger? Will happily provide more details if interested -- not that I've done everything absolutely right, of course, but like any experimenter, I just kept fiddling till it worked.

What immediately comes to mind is a small pocket AM band receiver with
a converter (and of course an outboard BFO); I've got several circuits
for converting HF to the MF broadcast band. I guess it's time to quit
posting transmitter circuits and give attention to some receiving circuits.
Oh, don't forget that project # 6 or 8 (can't recall) was a simple BFO
using an IF transformer.

Again, if anyone would like all 14 of the QRP circuits just write to me.
I think over 50 people so far have asked.

Project 15 will cause a riot - I was going to wait until April Fool's Day
to post it but I can't wait that long... (it's certainly NOT QRP)

> I am experiencing reciprocal mixing of signals on my SONY
>ICF-2010/2001D at about 24 or 25 kHz above the actual signal image.
>Is there something i can do to fix this? Tks.
>
>73 de 9V Daniel
>

Steve Whitt mentions a rather detailed (but simple) fix in his book involving replacing or adding 3 or 4 capacitors in the radio's IF section. It DOES involve moving a shield and some pretty detailed solder work so it isn't for the feint of heart or those with limited soldering experience though!

Has ANYONE reading this group done the mod to see how it performs? I haven't yet -- and have been trying to see if anyone else has before I tackle it to see if it really does make a difference. I have been getting more and more annoyed by the background "rumble" on 49 metres in the evenings here, and would like to try the mod sometime t see if it helps.

asirene@ntuvax.ntu.ac.sg wrote:
: Hi,

: Can anyone here give me some advice on building an antenna pre-amp
: for working 4 - 24 mHz? Should I go broadband or switched bands? What about
: pre-filtering?

The front end input preamplifier on page 25 of the February 1993 QST
might be a good compromise, offering 8 dB of gain and a 2 dB noise figure.
There is a good chance it will cover the entire 4 to 24 MHz spectrum as is.
A deficiency of this design is the necessity for good output matching--a
poor output match will degrade performance.

I prefer to use narrowband, fixed tuned filters, though there are
advocates of tunable filters.

: What are the advantages of designing one around bi-polar or mosfet?
: Can anyone contribute some tried and tested circuits for me to construct?

A problem with designing low noise HF preamps is that few, if any, devices
are optimized for this task. MOSFETs were primarily designed for use at
VHF and low UHF--specifications on HF noise figures seem non-existant. I
suspect that were someone to invest the $$$ for a really optimized device,
sub 0.5 dB NFs are possible. Occasionally, you can find bipolars optimized
for low VHF, such as the NEC 41603/2SC1949, touted as having a 1 dB NF at
70 MHz. The usual problem is excessive gain, which requires some form
of lossless feedback to reduce without degrading noise figure.
Theoretically, directional couplers could be used to implement feedback, but
I've not seen published circuits to duplicate.

Ok, top this great low power AM reciever for parts count.

```
Long wire antenna coil
--------------------) diode crystal earphone
)<----->|-------()--Gnd
)
```

Wind the coil on a toilet paper tube or a Quaker Oats box. The variable tap is the "tuning" adjustment. Volume is controlled by how deeply you stick the earphone in your ear. While this receiver is optimized for AM voice, it'll work for Morse too if the matching transmitter is spark.

hello all.
i'm working on a variable power supply (3-15V) for my sw radios.
i've gotten my hands on what looks like a good schematic. however, being
new at this, i can't figure out the (specific) transistors it requires.
there are two: an NPN and a HEP 232.
the most convenient place for me to get such pieces is at a local
radio shack. ..the catalog has alot of transistors...all marked either NPN
or PNP. i haven't spotted a HEP 232 (?). which one do i need? it gives
no voltage specs or anything. can i use just any old NPN? any help would
be appreciated. thanks.

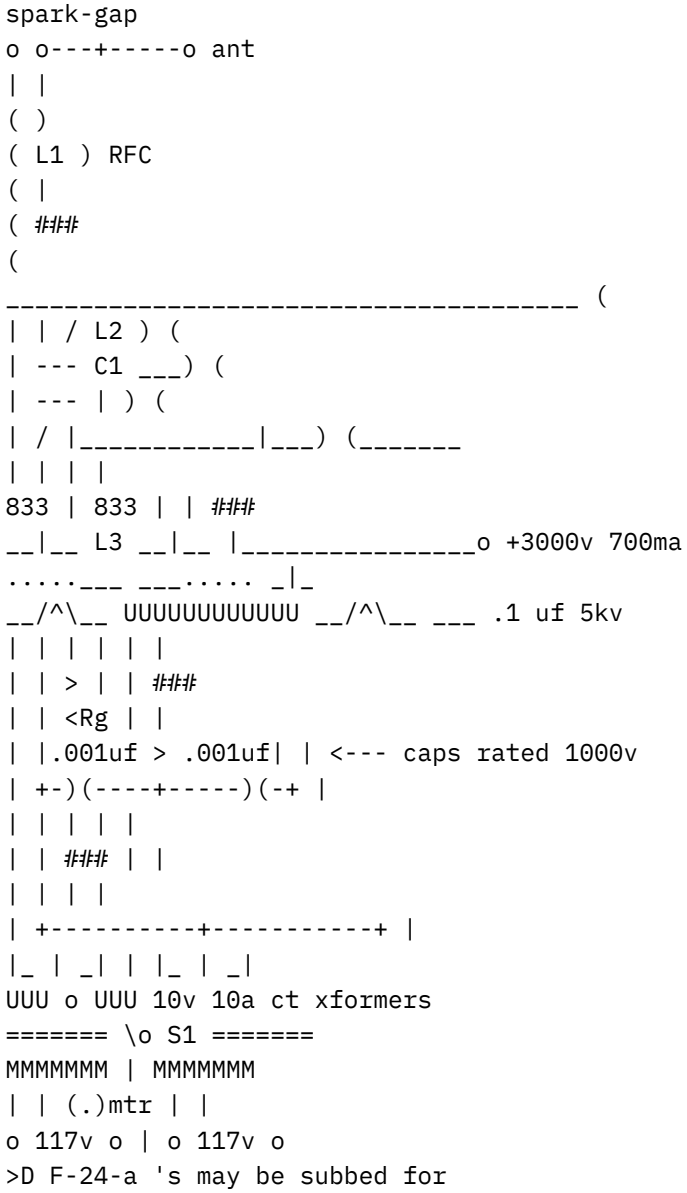
Gang,
If you actually build and attempt to operate this xmtr PLEASE do not
tell the authorities, when they come to pick you up, where you got the
circuit from (I'll deny everything).
Credit Randy, KA1UNW for the design. He's a prolific builder, specializing
in the design of QRP tube xmtrs, on our QRP mail net and on the boatanchors
mail net (although this is certainly not a QRP xmtr).
Remember boys and girls, this offer is void where prohibited...

TSB xmitter



| carbon mic 833's if supply's are made
larger.

How it works:

The 2 tubes form a push pull power oscillator which makes alternating
current, but at a radio frequency.
This is done by use of L1 , L3, and the 2 little tubes.

In this case, the actual frequency is not important, since the objective
is to generate maximum bandwidth...the goal of any 'phone station.
C1 is used to obtain maximum power by resonating L1 to L2's natural freq.

This RF voltage is stepped up by a factor of 30 to 100X by L2 and sent on
to the spark-gap, where the actual RF-to-be-sent is generated.

The RFC keeps the ant ckt at DC ground, yet will not short out the RF...which
is sent from the sparkgap, to the ant.

The ant wants to be one wire, and end fed. No coax required..just hook 'er
up and duck.

The length of the antenna determines the sending band it will be on.
The formula to use to get that length is...

Feet = 468/(((F*F) +730) -(F*F))

F = frequency in Mhz (rounded off to nearest 100 Khz)

Voice modulation is done by use of a special Carbon Microphone, as used in
the 1920's...which can handle several amps.

Here, rather than sending RF thru the mic as was done back then, only DC
is sent thru.

That way, the operator (or inflictor) won't get an RF burn on his lips if
he speaks too close to the mic.

That modulates the power to the tubes , which varies the intensity of the
spark which then puts quite suitable a signal on the air.
The itellegibility will match the content of some of the QSO's now on the air.

To operate:

1 Place mouth near carbon microphone.
2 Close S1 and adjust C1 for dip in current (mtr) quickly.
3 Make oinking and Mooing noises to indicate your presence to everyone.
4 Open S1 when you get around to it.
****

Again, credit (or blame) goes to Randy KA1UWN.

Yes, that's right they are used as jumpers. I makes it easier in the manufacturing process to put zero ohm resistors than wire jumpers, I guess.

OK. so shoot me if this is too simple.

Buy an MSA-1104 (this is in the large, easy-to-handle, plastic microwave package). I got some for $3.25/ea last week. This is a 50ohm in/out MMIC with 12-13dB of gain up to the Ghz range. It is capable of over 50mW of output combined with a noise factor of below 3.6 in the HF bands.

With DC blocking caps of 1000pF, a 100uH choke and bias resistor for 50mA of bias current, you'll have a no-pain preamp with a pretty good dynamic range.

If you feel like working just a little, try using a broad-band grounded gate J310; you can get about the same gain and IP3 but a noise figure below 1dB. Use a small ferrite balun core with a turns ratio of 4:1 (16:1 Z ratio) on the output, use a 220 ohm bias resistor, go to town. I bought a stash of J310s for $.34/ea; the additional components would make the total cost similar to the MSA-1104 circuit, with a lower NF.

On HF, a 3.5dB NF is not a big deal.

251. Build a simple 49 mhz reciever?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-01 07:06:38 UTC
From: adkinsg@rock-opera.cc.purdue.edu
Message-ID: <CKJAF3.BC9@mentor.cc.purdue.edu>
Source record: 118689

Hi all!

I'm wanting to play with the signals from my cordless phone, and I would like to build a simple FM reciever so I can digitize the signals between the base and handset.

The phone is a sony spp-75 with 10 "channels" operating at 49 Mhz (not one of the new fangles 900 mhz jobbies) The phone is pretty smart and won't turn on unless it can "talk" to the base.

I have a good scanner (RS pro-2004) but my dad has it and won't give it back. :-(So I want to build a simple analog tuner out of perhaps a cheapie FM radio. The only thing I care about is having the ability to digitize the "braaaap" of base/handset communication. I'll only be a foot from the base/handset so reception range isn't critical either. (Altho the computer will be on so I'll have to account for that hash..)

Any suggestions??

Thanks!
Garry

>: You should be worried about the coax feed also.

>Also worry about soft X-ray emission at 7kV - that kind of voltage with that
>amount of current pushing it should generate lots of low energy X-Rays.

Let's see. With an iron plate in the tube and 7kv, that should produce
X-rays with a peak energy in the 4 KeV range. That should be able to
penetrate oh, maybe 3 or 4 inches in air. It certainly wouldn't penetrate
the leaded glass envelope. Nor would it penetrate a ceramic/metal
tube envelope. A real hazard,huh? (NOT!) High current doesn't equate to
high energy. It only increases the intensity. A little knowledge is a
dangerous thing.

> 73 de 9V Daniel

A very fast way to find a 14MHz crystal is to remove one from
an old IBM PC clone. They all have a 14.31818MHz crystal in them, and
you should have some luck finding old turbo PCs, dead, very cheaply
(like free if you know where to ask).

Please use MHz if you mean 1,000,000 Hz. mHz is 0.0001 Hz.

gary@ke4zv.atl.ga.us (Gary Coffman) writes:

KE4V> Normally, a preamp is unnecessary for the HF spectrum.
KE4V> The usual problem is inadequate rejection of strong signals.

True, unless the antenna is too small.

KE4V> You definitely want to use a selective
KE4V> amplifier with good sharp tuned circuits.

I prefer passive pre-filter + wideband amplifier.

Wideband (say 2-30MHz) amplifier with moderate NF (~3dB), gain
(~10dB), and 3rd-order IP can be easily built using a pair of J-FETs
in parallel in grounded gate configulation. You can use 2SK125 or
J310. Many (most?) of Japanese HF transceivers employ similar circuit.
Akizuki [in Akihabara Tokyo Japan] sells 2SK125 (You can specify class
"5" for max Idss) at about 2 $US per 5 pieces.

Once you built wideband amplifier, you can play around pre-filters as
you like and study. It can be a bunch of bandpass filters as in the
case of manufactured tranceivers. Or it can be a tuned circuit with
variable C's and L's. Or it may not be necessary if your anttena is
really small.

KE4V> A power VMOS FET like the VMP-4 may be a better
KE4V> choice. Run about 100 ma of standing current.

Yes. But when I asked Ed Oxner about his nice VMP's a year ago, he
said that Siliconix had sold their factory lines for VMP-1 and 4 and
were no longer manufacturing them. Are they still available? Then I
would like to know where I can get them.

Meanwhile I purchased some T-MOS FETs from Motorola but so far haven't
had time to experiment wideband NFB preamplifiers using them.

Siliconix had discontinued VMP-1, VMP-4, U350 (U310 quad for DBM), and
Si8901 (DMOS quad for DBM). Why? I can't understand. Maybe they had
come too early and gone too early.

HELP!!!!!!!!!!
I ordered a couple of "assortment" packages from
ALL ELECTRONICS. Now, I could figure out what most
things were, but there were still some "mystery"
components that I just can't figure out.
FIRST, I ordered the 200 Assorted 1/4 watt ha
resistors for a buck assortment. (part# GRES)
I figure d out most of these except for two odd ones.
The first was a resistor with just a single black stripe
running down the middle of it.....what is it?
The second one was blue and had the following letter, number sequence.
P
RN55D
3572
FJ

Wellll.. I stopped my anti-social hardware tendencies about 5 yrs ago, and now
do mostly software... but... I believe an RN55D is a milspec 1% resistor. The
value would be 357*10^2 or 35.7KOhms. I don't remember what the FJ means...

What is this one?

The other assortment pack I got was just 200 assorted resistors, capacitors,
and diods. There were some things in here that baffled me as well.
First off, all the capacitors were strange to me. I;m used to radials and
disks, but these ones where different.
They had the following number sequences.
The fist one: 1M+ The second: .47 and the third: 1 62D
35V 2 35VK 1-35V
cicled< 8034+ 2+ 2+
Any help on these?

The first one is probably a 1uF 35 volt tantalum. The circle usually indicates the negative terminal.

The second .47uF at 35 volts -- the '+' indicates the positive terminal.

The third a 1uF 35 volt...

And, lastly, are the diods from this group.
There were a bunch of black (silicon?) diodes. The only mark they had
was a single yellow line on one edge. Any help here?

These could be anything -- the yellow line indicates the cathode end of the diode:

```
_________________|\|____________________
|/| yellow stripe end
```

two choices here -- test 'em and use 'em best as can in non-critical locations, or chuck 'em. (Or do like I do *plan* to test them, then explain to the XYL why I need 32 gazillion boxes full of parts &-)

Hope these aren't stupid questions. any help is much appreciated!
Thanks in advance!

256. Varactor tuned VFOs

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-01 18:31:38 UTC
From: greg@netcom.com
Message-ID: <gregCKK64q.DGC@netcom.com>
Source record: 118694

I've seen a few examples of varactor-tuned VFOs (not VXO's)
in various pubs from time to time. They've always, though,
been used in receivers... ...I can't recall seeing one
used as the basis for a QRP transmitter.

In wondering 'why?' I've come up with a hypothesis: are
they very sensitive to RF, in that stray voltage from
the transmitter tends to get rectified into the tuning
circuit, thus causing all kinds of amusing keying foibles?

Greg

257. Old Microwave Oven

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-01 18:57:11 UTC
From: ren@rap.ucar.edu
Message-ID: <2im8m7$908@ncar.ucar.edu>
Source record: 118708

Recently a neighbor threw out a microwave oven, being an avid
recycler and former uwave repairman, I was duty bound to take it
home. Well it operates, but it leaks radiation like crazy,
(I measured it with a Schottky Barrier Diode and an LED
but that's another story...) so I'm not gonna use it (I've got a
decent Amana anyway).
Soooo.....what can I do with it? I recall reading on the
net where someone thought the Magnetron and Pwr Sup. could be used
for EME morse code transmission. But what else?
Yeah, I know I could rip the maggie apart for a refridgerator magnet.
Oh yeah, it's an old style, i.e. motorized, not digital, timer.
And I also recall somewhere about cutting off the transformer
secondary wires and rewiring for a custom power supply...
So send me your ideas, and I will summarize...

The reason zero ohm resistors are used is because automated assembly
equipment can pick and place them where they couldnt pick up a jumper wire.

Nope, low on cash at the moment. And pretty much just starting in this
kinda thing. Most of the "mystery components" have been named now, but there
are still some that are odd. Lots of different answers to the same items.

However, I do THANK everyone INTENSLY for their help. It's obvious I need to
get out and purchase some test equipment. Thanks again, I now have names for
more than half the strange stuff I recieved.
Tantalium (spelling?) capacitors, 0 ohm resistors. So thanks again!!!!!!!!!
The blue resistors are what seem to baffle others. I got lots of different
answers on those!!!!!!!

I know that I am posting this instead, but maybe someone else on the net can help with this. I remember reading in an old issue of 73 (I know I have the issue in my basement) about a guy who took a microwave, and made a portable ATV station out of it. I can't remember how he did it (I didn't have my ticket then), what really sticks out in my mind is that he was able to use the cooking cavity to hold all the cameras, mountings, etc....

Anyone else remember this??

(If you can wait a little while until I go home (1-3 weeks), I will try and dig it up)

Hi,

I am in the middle of getting parts for a 20 meter QRP transmitter. Can anyone direct me to where I can find 50 pF variable capacitors (not trimmers) with spindles which can be panel mounted? These should be air-spaced ones I guess, for the VXO.

Another thing, what is considered a fundamental frequency xtal? Are the 14.318 mHz crystals found in the TV sets considered fundamental 14.318 mHz xtals? Or should I be looking for something different?

Well you could rip off the door, jimmie the door switch, hang it
from the side of your tower, hook a giant morris kode key up to
it and send nifty secret messages to your buddy across the
neighborhood with the LEd and the Schottky diode :-)

The SO42P is from Siemens. I am not sure if anyone else produces it.
I do have data sheets for that IC. I would imagine that the 1496 is
functionally equivalent to it, but not a pin to pin replacement.
You could probably get the Siemens IC in Europe ;-)

Hope this helps, Peter

The address of the LWCA (as of '91, anyway) was/is:

45 Wildflower Road
Levittown, PA 19057

They will likely send a sample copy of their publication if you send them
a buck and a LARGE SASE (i.e. to accomodate the size and weight of a
publication that is 8.5" x 5.5" and up to a dozen sheets...)

Recent 73 Mags (Jan, Feb, and March, presumably) have had an article on a
WWVB receiver for the purposes of using its 60 KHz signal as a local frequency
reference.

: should be adjustable.
```

Adding to Jeffs info.....

Knowing the freq and the inductance, do this formula to find C

25330

F^ * uh F = mhz ^ is 'squared' (F x F)

Now multiply C by 1.5 and 3 to get the 2 caps values...and BINGO! you
will be close to a 50-75 ohm Z output

Diddle the coil to get cleanest keying.

The coil will want to be a value between 3 and 20 uh for 80 mtrs, for an absolute min/max workable value.

===

Jeff.. I tried the ckt out and 15 uh , 180 uuf and 330 uuf worked with a 3579kc xtal....but I had to place a bit of ferrit slug by the coil to make it key nice into a 68 ohm resistor load (I'm a tek so, I can't air the thing)
I used a 2N3053 (NPN) so I had to turn battery umop apisdn .

Hey...where is that zillion volt spark thing I was hearing about?
Can't find it in homebrew....

277. Re: Antenna pre-amp design. Help!

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-02 21:28:47 UTC
From: steve@hi.com
Message-ID: <steve-020294152359@brainiac.hi.com>
Source record: 118714

I'm new to RF design. I've been reading the ARRL handbook, Bowick's book, Hayward's book, QEX articles, etc. I haven't seen any discussions of how to estimate the dynamic range (3rd-order intercept, etc) of a wideband RF amp.

I suppose one could obtain a good spice model of the device and do a large-signal analysis to obtain the 3rd-order intercept. Alternatively, if one had good instrumentation in the lab, one could build a prototype and measure it. I don't have spice, and I don't (yet) have much in the way of instrumentation.

Are there any design rules-of-thumb for a large dynamic range? Are MOSFETs better than JFETs in terms of large-signal linearity? Are JFETs better than BJTs?

I suppose part of the answer is negative feedback. I don't see much in the amateur press on negative feedback techniques for wideband RF amplifiers (or for IF amps, for that matter). Can someone recommend some good texts?

Thanks,
-Steve

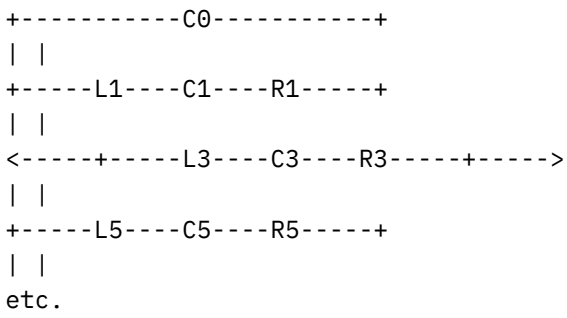
: Another thing, what is considered a fundamental frequency
: xtal? Are the 14.318 mHz crystals found in the TV sets considered
: fundamental 14.318 mHz xtals? Or should I be looking for something
: different?

Any crystal can be made to oscillate on either its fundamental or overtone frequencies. The overtones occur at APPROXIMATELY odd multiples of the fundamental frequency. Note that while harmonics occur at precise multiples of the fundamental, overtones are only approximate. When a crystal is oscillating on an overtone, no fundamental energy is present. The equivalent circuit of a crystal:



C0 is the shunt (holder) capacitance. L1/C1 determine the fundamental frequency, L3/C3 the third overtone, L5/C5 the fifth overtone, etc. As you can see, the crystal is resonant on many different frequencies at once. An "overtone" crystal is one specially designed and specified to work at one of its overtones.

If your oscillator does not include a tuned circuit, it will likely oscillate at the fundamental frequency, because most transistors (and tubes) have more gain at low frequencies than high frequencies. Also, R2, R3, etc. are usually larger than R1, so the oscillator "wants" to oscillate at the fundamental.

To get the oscillator to oscillate at an overtone, you need to include a tuned circuit or other frequency-determining element in the circuit to "kill" the gain at the fundamental frequency and force the oscillator to oscillate at an overtone.

Most crystals below 20 MHz or so are fundamental. Above 20 or 30 MHz, most are overtone type. Your 14.318 MHz unit is probably fundamental.

NRaD RADIO COMMUNICATIONS NETWORK

We are beginning a new mailing list for the
professional radio communications engineering
community. rec.radio.amateur.* is a well
established source of information for radio
hobbyists, but it does not meet the needs
of many commercial, military, and academic
professionals.

Therefore, we are hoping that this mailing list
will somewhat fulfill this need. Relevant topics
include: radio propagation, antenna design,
hardware design, FCC regulations, industry trends,
parts suppliers, military requirements, and
so forth. We would prefer that hobby-oriented
topics remain on the established newsgroups.

To subscribe, send a message to me at:
martinb@cod.nosc.mil

I will add your name to the list and send you an
informational message about the operation of
the mailing list. If you wish to unsubscribe,
send me a message, and I will remove your name from
the mailing list.

I've got the enhanced version of FFTMorse put out by Rocco Caputo and for the life of me, I can't get it to work with my SBPro CT1330Rev 2 card. The program refuses to recognize my card despite the fact that I've updated the CT-Voice.drv to 2.1 and changed iterrupts/reinstalled from scratch/ etc. The card works well otherwise; just can't get Morse.exe to recognize it. It reports a card type -1 which Rocco says means that it does not recognize my card as a valid type, so my BLASTER var (a220 i5 d1 t2) is of course deemed to be wrong, and the program terminates.

Anyone have a similar problem, and played with the
morse.exe C source code to fix this annoying fatal error??!!
Or will I be forced to go to HamBlaster.....

gap

I know this uses more modern tubes (50's 60's) but someone pointed out
that the older design is likly to radiate when in CW/SSB mode and could
qrm someone who is close by,if one does not get tuned in properly.
Only those experianced with such a set should try to use it!

This one...if built in a metal chassie with a bottom cover, and V1 gets
a tube-shield, and tune cap, coil are INSIDE.....it will not bother
any one except someone within 100-200 ft , worst case...then you'd only
need a cats-whisker radio to hear em!

I built this one some time ago, and had it on many bands to SWL with.

A bonus here, is it will want a coax cable feed, to a conventional ant.

Coil: P is to be about 1/2 the turns of S and the tickler will be
1/15 1/20 th the turns of S
observe the phasing as shown by the x on each coil in diag.

Coil dia...can be as for #77 regen set...or you can use a smaller dia,
and have to use more turns!

Coil form should be well anchored to the chassie by use of a long #6-32
machine screw and 3 nuts, to 'side-angle' mount it:

```
make snug
,---, /
(| |[]######[]## # = screw threads
head / |. | n n n= nut 3rd nut goes outside
| | on top of chassie.
| |coil form . = hole for to fish wire inside form
| . |
|. |
| ::| <--- double holes to fish wires thru
|___| 6 needed...use PCB board drill (carfully!)
```

xxxx on chassie shows which way to mount it. 0 is where 3rd nut goes

Adjust the 2nd nuts position so the coil is equally away from chassie-top
and the bottom cover...then sock-down the 3rd nut to lock it all in place.

By making the coil's wires run over to a solder-lug strip, it allows easy
removal for doing experimental work on the coil.

A plug in coil will work, but the objective is to have it well shielded,
which gets involved to do that with a plug in coil....unless coil is IN
a small can or mini-box...and a 6 pin plug is used...going to a 6 pin jack
on the chassie.

For those who want a coil for a specific freq/band I can give out that info
once I know what band is wanted.
Yes..it will work LOWFER band...if ya add one cap paralell to the tune cap.

For LOWFER, a store bought 1 mh coil is best (ya feel like winding 400 turns?)
for coil S...Digikey sells nice little and low cost ones that are just fine.
That takes care of that coil...then...you can...
fiddle with how many turns for coil P and tickler.

The 1 mh coil goes INSIDE the pvc pipe...and coil P and T are wound outside.

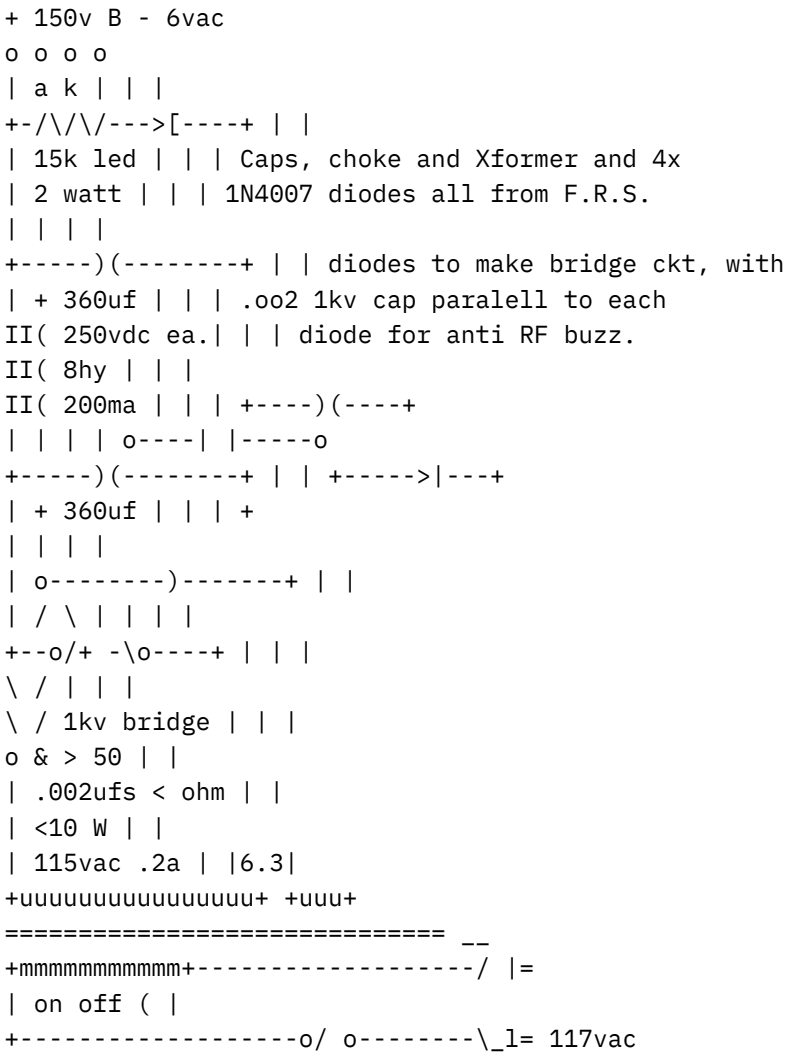
SHORT WAVE:

If you use other than 140uuf then the coil uh will need be different.

Caps of the 90----400uuf size (max mesh values) are OK here...and for LOWFER
the 300-500uuf sizes are better....the added cap is to be 680 uuf.

Fair Radio Sale and Antique Electronics supply combined, will have all the
parts you'd need...along with a hard ware store.

Use this power supply or either of the ones given before



+ 150v B - 6vac
Caps, choke and Xformer and 4x
1N4007 diodes all from F.R.S.

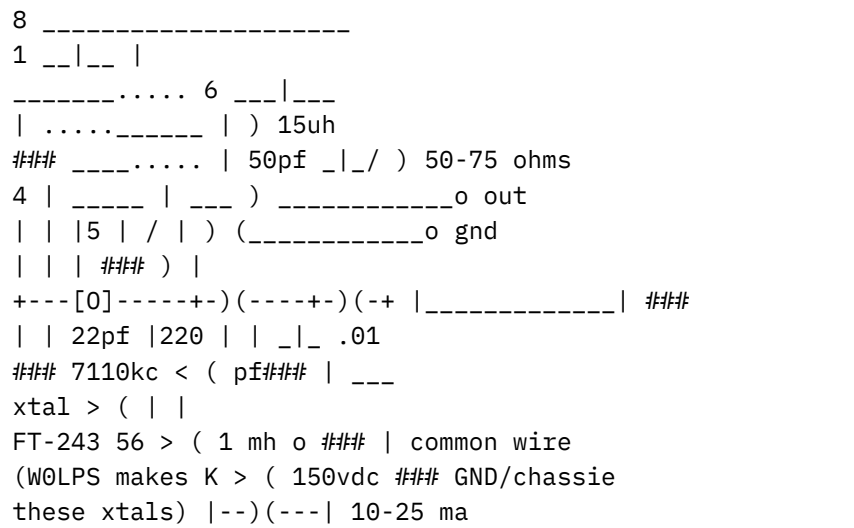
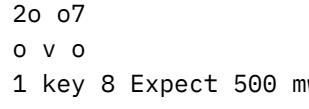
287. 1 tube transmitter, 6AG7

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-03 04:43:26 UTC
From: randy@cyphyn.radnet.com
Message-ID: <1994Feb3.044326.7463@cyphyn.radnet.com>
Source record: 118576

6AG7 one tube xmit 40 mtrs (daytimer)



Tube socket, BOTTOM view



15 uh ... 35 turns 7/8" dia, 1 " long
link coil 6 turns #22 to 28 wire OK

50 pf ok if FRS's 55pf trimmer cap
Xtal W0LPS (CW Crystal co)
Tube socket FRS or Antique Electronic Supply (AES)

150vdc is from the supply given earlier
6.3 volts, from same.

You can run both receiver and transmitter off same supply

Note...a 6CL6 or 12BY7 (different socket wiring) will work the same
as this one will....so, a sub of tube (and rewire socket) can be done.
Those 2 tubes are 9 pin mini tubes
12HG7 will sub 12BY7 directly. (if ya need info on that, buzz me)

Note... a 5902 sub-mini tube (direct-solder in like a transistor)
will also work in ckt above, but B+ must be dropped to 90-120vdc.

Tune up: Altho a 3 volt 25 ma bulb in series to the key will work as
a current indicator, you can use station Rx set to tell when it is
correctly tuned (least chirp & raspyness as you key).
Full power does not quite occur at same point as best keying does...
no loaded osc ever does....but you'll have same S-reading 'out there'
so just go for a clean sig.

Start with the 50pf at full mesh, tap the key repeatedly and adj
the cap until you hear the signal (see it on bulb as a sudden change
in britness)..or see it on a watt meter (good luck!), if it can read
that low.
Then adj for cleanest signal.

291. Old Microwave Ovens > New TV Xmitter

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-04 15:10:58 UTC
From: stevej@pillock.moron.vware.mn.org
Message-ID: <Zoa9gc1w164w@pillock.moron.vware.mn.org>
Source record: 118581

A bit of History:

In about 1986-88 the British Amateur Television Assoc. published in their newsletter a spoof article about using the magnetron tube in a microwave to create a 2.4ghz FM TV transmitter. I do not remember the author.
There was a lot typical british humor thoughout the article but in the end my buddy Chris (G4JEC) and spent weeks arguing whether it could be done.

Fast forward to June 1989:

I had just received my July issye of 73mag and on the front cover in small letters "Microwave oven ATV is here!". I was ecstatic when I saw the article and I must have laughed for 5 minutes. My oven is still in the garage

The title of the article is:

ATV Transmitter from a Microwave Oven!
Author - David Pacholok KA9BYI
Page - 54

>73 de 9V Daniel

This is a real standard circuit. Two things to remember, though:

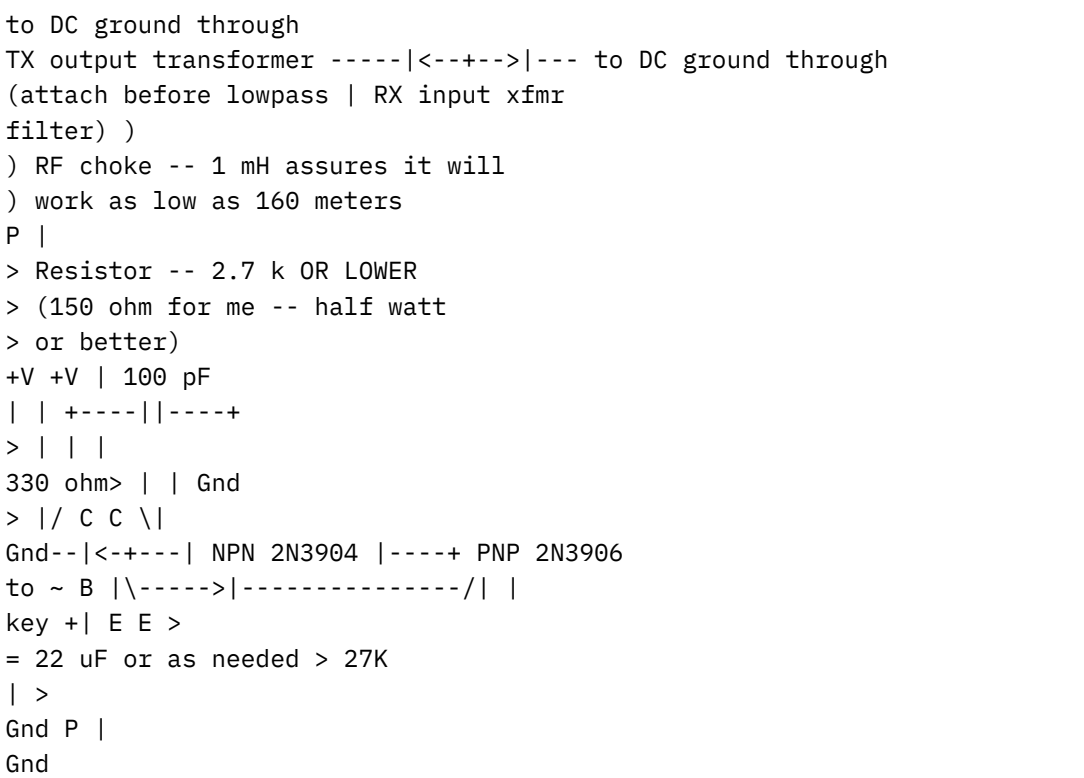
1) On transmit, the 51 pF cap becomes part of the first shunt leg of
the output low-pass filter. Compensate accordingly.

2) You CAN add a series inductor that resonates with the series
capacitor on receive to reduce signal loss. Lots of articles recommend
this.

In ARRL's "QRP Classics", page 272, they recommend a capacitor with a
reactance of 400 ohms, which means 56 pF at *40* meters (lower for 20
meters). Other articles in that collection use the series tuned circuit
approach.

As you can see, this is a problem for a broadband situation, plus it
means a received signal *loss* even under the best of circumstances.

That means you should probably consider a true active diode *switch* to protect your receiver. It works better anyway, though it consumes more DC current if that's a portable concern. My switch was taken from QST Hints and Kinks, July 1990 page 38, with added switching circuitry -- a separate transistor switch (ground a + voltage to ground to turn off) with correct time constants to stay "off" until the keyed CW envelope goes to 0. You may not need the NPN switch depending on what your TX provides -- you could take it off the keyed voltage to your keyed stages. But I needed independent control of timing to tame a "spike" of full RF power on key-up. 1N914's work fine for around 5 watts
Of course, you may need another RF choke for the ground return if by some chance the RX input doesn't go to DC ground.



to DC ground through

I needed a LOT of diode current -- about 50 mA -- to assure enough conduction to eliminate broadcast interference from a 50 kW AM station about 5 miles away! You may not need this much.

This is my method. I'm using it with the Campbell R2 receiver, Jan 93 QST. I also have an RIT circuit that switches two pots to adjust the voltage to a tuning diode -- I have both a transmit and receive offset pot on the front panel, with a switch to select only the transmit pot for spotting or SSB. With a very fast time constant on receive recovery, I can hear between dits and dahs at about 15 wpm -- I don't run much faster than that at QRP power!

294. Re: Varactor tuned VFOs

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-06 11:32:46 UTC
From: trier@odin.ins.cwru.edu
Message-ID: <2j2kgu$bg@usenet.INS.CWRU.Edu>
Source record: 118583

There's no reason not to use one in a transmitter. The problem is that they tend to drift with temperature changes.

Given that good air-variable capacitors are expensive, the future may have more varactor designs. You won't see much of a dent until the air-variable junkboxes start to empty.

If you want more stability, you need a feedback loop. A PLL or a frequency counter (a.k.a. a Human PLL) would work.

Stephen

: used as the basis for a QRP transmitter.

Actually, in a sense, there are a whole lot of them: as VCO's in PLLs in things like handhelds. As someone else pointed out, they aren't particularly temp stable, but a bit of feedback can solve that problem. And you can frequency or phase lock them quite easily: frequency locking is especially easy, since if you assume that the VCO won't drift too much in a single count period (say 1/10 second), you only have to keep track of the least significant bits to get enough info for a correction. Continuing the example, 4 bits of count could correct +/- 70Hz each 1/10 second, and if you feed the correction into an integrator, it will track. If you have a drift that large, you probably need to work on the open-loop characteristics anyway, before closing the loop. Anyway, the result would be a 10Hz reference, a 4 bit counter, a 4 bit latch to save the "desired", a 4 bit adder (actually subtracter) to find the error, a 4 bit DAC (4 resistors driven from the CMOS output of the adder), and an integrator. You could put all that in a FPGA (including the reference generator and timing stuff) pretty trivially. But you can also do it with common parts that have been available since the late '60's...

(Refinements are possible: for example, you can make the "DAC" nonlinear so that if the frequency is close, undersize corrections are made, so that there is less "hunting" tendency.)

This has probably been covered many times before. In any case...
Can anyone suggest a design for matching a 50-ohm coax feed to a six beam,
2 meter Yagi. The balun designs I've seen all seem to be restricted to
frequencies less than 100MHz. There must be a classic technique, I just
can't find it!

I use a dual band Icom HT in the car. Having bent longer aerials, I now use a 1/4 wave. I could do with more 'oomph' but find commercial dual band linears excessively pricey - typically between 250 and 400 UK pounds.

Can anyone give me pointers to published designs or suitable circuits to build one myself? Other comments or suggestions welcomed.

Thanks

David (GM0SYA)

Sorry that was T/R relays (I didn't see it till the next round). I just called them - Their UHF amp is 28V, but they are hoping to have one for 12V by Dayton. I think their VHF amp used to be 28V, but now it's 12V. I'll keep me eyes out. Thanks for the tip.

These are essenitally the same transistor, at least as far as QRP projects
go. I stocked up on J310s from Hamilton/Hallmark, which is at least as
good as the 2N4416/MPF102, for $.34/ea brand-new.

The HEP line was made by Motorola and I believe HEP means "Hobbyist
and Experimenters Parts". My NTE book says it is equivalent to an
NTE 121 a PNP power transistor in a TO-3 case, 30v c-e, 100 watts.
It is also germanium. The closest radio shack equivalent would
be a part # 276-2043. You might have to twiddle with the biasing slightly
because the RS part is silicon. Generally transistors for this sort
of application are pretty non-critical as long as you have the
approximate power dissipation and collector voltage.

The classic solution is Q-dope made by dissolving polystyrene
in a solvent. Polystyrene is plentiful but I can't remember
the proper solvent. I made a gooey useless mess once when I
used a less than optimal solvent. Acetone should work.

>These are essenitally the same transistor, at least as far as QRP projects
>go. . .

Although usually true, there are a couple of common applications where substituting an MPF102 for a 2N4416 might cause a problem. These JFETs are commonly used as an oscillator, either Harley or Colpitts. In these simple oscillators, the oscillator output amplitude is directly related to the individual device's pinchoff voltage. The MPF102 has much looser specifications, so in some cases will deliver too small (or large) a signal when used in one of these oscillators in place of a 2N4416. Of course, you can make up the difference in a following stage if it's a one-off design or you're willing to put in an adjustment.

The other application where you might have a problem is using the MPF102 for a common-gate RF amplifier. A typical application runs the JFET at Idss and couples the signal in through a 1:4 impedance ratio transformer. With the 2N4416, this will result in an input SWR of 1.5 or less; the MPF102 can present a mismatch as high as 2.5:1 because of its looser specs. This may not cause a problem, but it could reduce stage gain. Or if the common-base stage follows a filter, it could result in degraded filter performance.

You can always substitute a 2N4416 for an MPF102 (unless the metal case on the former causes a problem), and except for the two applications above, the reverse substitution is usually ok too.

>can't find it!

The classic VHF balun technique is the quarter-wave sleeve balun. In old days these were often called beer-can baluns, so named because steel beer cans were soldered together to form the outer sleeve. KLM and a few other companies sold these commercially but they are easy to build with copper tubing and pipe. Design information can often be found in the older ARRL VHF manuals. 73

There have been a few letters published in QST mentioning the device-to-device variation of the MPF102 can result in considerable performance changes. In particular, the use of the MPF102 in an oscillator is rather mentioned; you just about have to hand-select a FET out of a batch for best/correct output.

I've never really looked at it hard, but most oscillator circuits that use a JFET include a diode from the gate to ground. This obviously serves to clamp the gate voltage before the gate/source diode conducts (as long as the diode is fast enough :-)), and also will build a DC offset on the coupling capacitor from the tank circuit to the gate. This DC bias would appear to, and is said to, provide an AGC action is stabilizing the oscillator output amplitude. What comes to mind, is this action adequate to compensate for common device variations?

Yup; I always recommend using a J310 for such an application since (a)
the specs are tighter and increase chance of repeatability and (b) the
fairly high forward Gm of the J/U310 provides a pretty good match directly
to 50-75ohms.

I have a question that is possibly a little out of place here in your news group, but for lack of a better place to post...

I'm not a HAM-ster, but I'd like to build a headset (Microphone/earphones) w/ a built in transmitter reciever for use w/ my computer. I'd like it as compact as possible. i.e. all in the head set wo/ a battery pack.

This will require at least two (three if I decide to go stereo) IC's (RS-232), plus possibly a very small pre-amp for the mic (this will depend on output levels on the mic and required input levels at the IC.)

Does anyone know where I can get a design for such a project? Or better yet, has anyone ever built that sort of thing?

Any info, hints, tips, tricks, or possible "hang-ups" would be greatly appreciated.

Does anyone have any experience building or playing with the DDS board designed by VE3JIL and published in the August '93 issue of '73? It is a parallel port controlled 0-16Mhz synthesizer. I am interested in using it in a 432 Mhz receiver which requires a couple of frequency doublings and I'm wondering if the performance of this board is equal to a VXO in terms of stability, phase noise etc.
Does anyone have any other DDS designs that are worth considering? There are many chipsets out there but most are far too expensive for this application.

No. The diode limits the positive excursion of the gate signal. Pinchoff
determines the negative excursion.

check the back of QST, there are a couple of manufactures of nice little boards (about $50 I think), you can build a simple 100Hz osc and inject that into your input audio, it is hard to build one that doesn't drift though, a Wein Bridge osc is OK but the XTAL controlled boards are better, I'd buy one, then you can change the freq if you need to, the have little jumpers or switches to set the correct PL,

the 100Hz needs to be abouut +/- 1 Hz, people on the air can help you set the deviation level.

good luck

Hmmm, this scheme would allow analog tuning that "snaps"
to 10 Hz increments with the long term drift characteristics
of a crystal reference. Neat.

Neat! One of those Microchip PICs could do the job nicely, replacing the adder and 10 Hz reference. (Software timing loops could do the job.)

Are there any other clever ways to reduce this scheme to fewer off-the-shelf components?

>wo/ a battery pack.
David,
I didn't build one of these, but did "hook together" some parts for a
similar project. I wanted to have hands free operation at my computer
while talking on the phone. I tried all headsets I could find (Hello
Direct, Plantronics, etc, etc) but was disappointed with the quality, and
needed more noise cancellation (I enjoy being in my own world).
I finally got a Peltor Helicopter Headset hooked it up to a small
amplifier (from Plantronics) and a small impedence match for the
microphone, and I am happy! Not to mention 27dB noise reduction!
I look like "geek-of-the-week" at my desk, but hey!

It isn't that simple. You must design the integrator very carefully in
order to do so, and insure that the setting time of the VCO is under the
1/10 limit. And then, take care that there is no oscillations.
For this kind of application, you need a third order low-pass integrator,
because a second order won't follow the correction speed.

<warning: I got paid for the articles mentioned in the
following. Not well, not enough to cover shipping and phone calls,
but I *did* get paid...>
No, I have not built that DDS, though I suspect it will work
out poorly (as would most DDSs). The problem would be phase jitter,
and it would get worse with multiplication. A possibly better
approach would be to use a crystal oscillator for the multiplication,
and mix with a DDS as the VFO. This gets you up where you want
cheaply, and gives you the fine-tuning and wide coverage that you need
up at 432MHz (it's a big band :-).
As for other DDSs... In December 92, January 93, February 94
and March 94 of 73 magazine, there were various parts of a DDS (the
VFO, a pitiful excuse for an amplifier (guilty as charged 1/2 :-), a
diode programmed board, a parallel-port programmed board and a
thumbwheel-switch board). It is based on the Qualcom Q2220 chip,
using a Harris CA3338[A]E DAC, and it runs from just above DC to
21.5MHz in 3-ish Hertz steps (10-ish if you use the thumbwheels). It
is designed as a bunch of building blocks, so you can change parts as
you want, with receiver, SSB, microcontroller (and a better amplifier)
to follow as I (or anybody else) get them designed & tested.
There are people selling various kits for these articles (I'm
NOT one, and I get no $$$ from any of them, so this is not an
advertisement...), and they are (relatively) cheap (around ₰100 for
the VFO, $80 for the thumbwheels, $??? for the parallel port (don't
buy the amp, skip the diodes unless you are *really*
cheap). It is spectrally clean enough for HF QRP regulations (QRO if
you stay below about 10MHz), and it is not only a good, stable VFO but
a pretty handy signal generator (need a 700hz tone? a 3kHz tone? Make
a dc receiver for 17 meters? Sweep a crystal filter?).
There have been other DDS articles in ham-ish publications.
There was one many years ago in QST (dunno much more about it), one

using TTL chips in Radio Electronics (covered up to 512kHz in 1hZ
steps, dip switch programmed) and the ones in 73. Lots of theory and
explaination articles in real radio magazines, but not a lot of
how-to-build-it articles there.

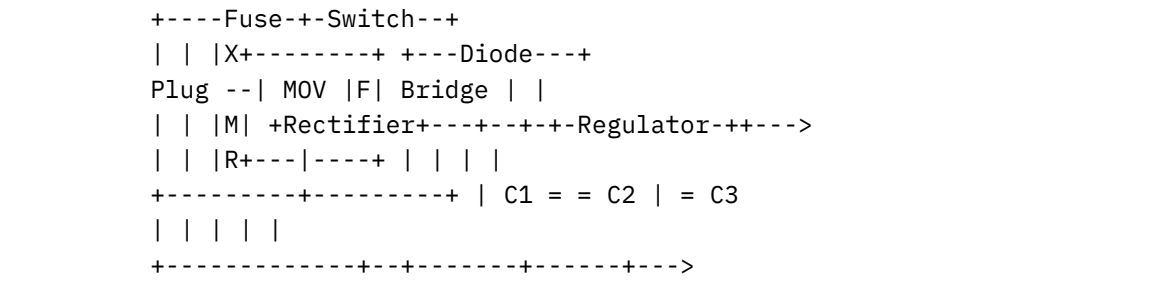
329. Power supply design questions (sort of long)

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-11 20:02:37 UTC
From: cravitma@cps.msu.edu
Message-ID: <2jgo8t$17cu@msuinfo.cl.msu.edu>
Source record: 118619

I am trying to design a regulated 12V power supply (to power my HT at home) and need advice on the following (since it's been a long time since I have designed P.S's and am going from memory). Here is the circuit I have so far:



The secondary of the transformer is going to be around 14V 1.5 A, and the regulator will be a 7812.

My questions are:

1) Have I overlooked anything electrical-wise or safety-wise in the circuit? As I said, it's been a couple of years since I designed a P.S. and I was going from memory here.

2) What are the values of C1, C2 and C3? (Capacitor type, capacitance and voltage ratings)

3) Can the 7812 handle 1.5 - 2 A of current? If not, is there another fixed 12V regulator I can use (I don't want to use an adjustable regulator for reasons of cost and simplicity of circuit design)

If anyone can provide comments, suggestions, criticisms, pointers to references, etc, I would greatly appreciate it.

Precisely what I was getting at in starting this thread. One thing that drives me bonkers about so many QRP designs is the XTAL control. A good, versatile, inexpensive VFO would be a godsend. I'm an experienced QRP type, but have rarely been rock-bound (Argonaut, you know), and I think I find crystal control a lot more limiting than low power.

However, the field of simple VFOs seems a bit neglected by the simple circuit gods.

I thought towards varacter tuning because they, and 10-turn pots, are a lot more obtainable than decent variable caps.

Well, we had the simplest xmitter thread, so I thought I would start a simplest code practice oscillator thread. I (and maybe some of my kids) are thinking about getting a ticket, and I'd just as soon not go the no-code tech road (couldn't tell you why though). Seems like I saw a circuit with six components: key, speaker, battery, transistor, resistor and capacitor. I think I even built it, though that was two decades ago. Every circuit I've seen recently, though, had more components and was fairly generic (few component values). I have an old TV, which has everything except the key and battery (which I have). Who's got a circuit?

The standard 7812 can't handle that much current, it's rated at 1.5A max, but there are "high current" versions that can handle up to 5 amps. They're usually the ones in the TO-3 cases and have the 'K' suffix on their part numbers.

The secret of the year seems to be the Analog Devices AD7008 DDS with on
chip DAC. This unit will provide 32 bit tuning resolution and a 10
bit DAC. Included are registers for AM an Phase modulation. All this
in a 44 pin plcc package.

339. Re: Question about Super Dual-Band J-Pole

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-13 17:48:59 UTC
From: djohnson@acpub.duke.edu
Message-ID: <2jlp6b$9vd@news.duke.edu>
Source record: 118629

I built the antenna from last Apr 73, and it seems to
work well on 2m, but it didn't do as well as an HT with
a whip ant on 440. What's up?

SWR is in OK range, less than about 1.5:1, on 440.

A more pointed question is:

Should I expect to be able to improve the performance
on 440 by experimenting with the positions of the
feedline taps near the base of the antenna?

This is my 1st j-pole. BTW, the tests of performance
were done using several local repeaters, and with the
j-pole mounted about 25 ft above ground, as compared to
results from the same rf source, an Alinco 560 ht, using
a whip ant mounted on the ht and operating from the 1st
floor in the house. I'm not sure what design the whip was;
it was my friend's flexible, fixed ant of about 14 inch
length.

This was disappointing performance on 440 !
Was I hoping for too much?
I thought that the gain should be even higher on 440 than
on 2m, NO ?

Sorry for not posting with the exact same thread name;
this is my 1st post ever on i-net - still learning to use
the reader!

Thanks for any and all input!
72, Dave WA4NID.

Hey how is it going up there in Ak. I grad from UAF in 92
What dept. are you in?

: 1. What exactly is a varactor diode??? What
: does it do? Where do I go about purchasing them?
: I can't find any in the catalogs I have.

varactor diode- variable reactance, this type of diode when reversed biased changes capacitance when a voltage is applied. These diodes are use for many thing, one application is a voltage controlled oscillator another is frequency modulation. Pretty handy parts..check out the ARRL handbook. professor Merrit up there at the EE dept has a few copies.
Motorola has many types of diodes you can probably get a sample from them, Newark or digikey should sell them but I think they both have $25 limits on there orders.
: 2. Are enameled wire and insulated wire the same thing?
enameled wire has enamel on it usualy a clear coating of enamel that you can scratch off with a knife. I have used this for winding RF chokes etc..

: 3. In relation to number 2 up there....when wireing your
: own toriods, is wire size, and insulation incredibly important?
: It seems like they would be, but a friend of mine said that
: as long as the wire size is close to what it says, than it would
: be fine.
Ya, close enough. you can get enameled wire at Radio Shack there on Cushman street. More importantly you should check that the toriod is made of the proper material, iron powder or ferrite. Make sure you don't saturate the core. The core materials are highly frequency dependant. Make sure your wire is large enough for the current you want to use.

: Anyway, thanks AGAIN!!!!!!

> 2) What are the values of C1, C2 and C3? (Capacitor type,
> capacitance and voltage ratings)
>
Assuming C1 is your main filter cap, C2 is not needed as long as
the regulator input is within a few inches of C1, which is probably
true in your case. The purpose of C1 is not to provide "pure" DC,
only to keep the voltage at the input to the regulator from going
below the drop-out voltage of the regulator. For a standard 12-volt
regulator, this voltage is typically spec'ed at 14.5 volts. C1 will
be charged to a maximum of 14 * sqrt(2) - 2 * 0.7 = 18.2 volts
every 1/120 of a second in the bridge rectifier configuration
(Transformer peak voltage minus 2 diode drops). We need to choose
C1 so that it will loose no more than (18.2 - 14.5) volts at your
maximum current (1.5A ?). Using i = C * dv/dt, we get C1 = 1.5 *
1/120 / (18.2 - 14.5) = 3380 uF. A 3900 uF @ 25 volt aluminum
electrolytic is the closest standard value, or you could use a bit
bigger cap. for insurance against low line voltage, etc. Note that
C1 is polarized.

C3 is a 0.1 ceramic.

The diode across the regulator is not necessary unless you have a
large capacitance on the output of the regulator.

Doug DeMaw's W1FB Notebook series has a number of VFOs meant to be dropped into crystal QRP designs. In fact, most of the radio designs in his books ellide the oscillator(s). That's an invitation to mix-and-match with a VFO if I ever saw one.

The most polished VFOs in his books are all based on air-variables capacitors. He has a few sample schematics for varactor versions, but no PC board layouts.

One thought I had: The problem with varactor stability is changes in capacitance as the temperature changes. What if one used an oven to stabilize the temperature? Is this practical? (Now someone will tell me HP and/or Motorola have been doing this for 25 years... ;-)

346. Re: Varactor tuned VFOs

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-14 14:34:07 UTC
From: kirkland@bnr.ca
Message-ID: <1994Feb14.143407.4204@bnr.ca>
Source record: 118636

Part of the problem with varactor tuned VFO's is that any noise on the tuning voltage will modulate the VFO - this includes both internal and external noise sources, e.g. thermal noise within the varactor due to its resistance and power supply noise. In tuning a VCO a good low noise voltage source is needed. Randall Rhea in "Oscillator Design & Computer Simulation" says that he avoids the use of the "bipolar monlithic voltage regulator" as a power source for oscillators as they have unpredictable and erratic noise performance (note the use of input/output caps (0.1 uf) on these regulators to prevent oscillation). He states that zener diodes are also noisy but generally less erratic, but with output R-C filtering, they are a better selection than inexpensive monolithic voltage regulators. One would expect that these ideas apply to the voltage source used to tune the VCO as well.

>I can't find any in the catalogs I have.

A varactor diode is a specially characterized semiconductor junction which, when reverse biased, has a known capacitance versus voltage response. All reverse biased semiconductor junctions have a variable capacitance in response to variable reverse voltage, but the value of the capacitance can vary from device to device. Varactors are made to have specific characteristics. Note that this means that you can often use regular rectifier diodes as varactors if you aren't concerned with a particular characteristic. Motorola makes an extensive line of MVxxxx varactor diodes. They're available from most Motorola distributors, and mail order places like Digikey carry a few different varactors.

>2. Are enameled wire and insulated wire the same thing?

Enamel is a way of insulating wires. It's basically paint. Other methods of insulation use plastic, rubber, or paper wrappings. Enameled wire is used primarily for winding coils because the paint is much thinner than the other types of insulation so you can get more turns of wire per inch.

>3. In relation to number 2 up there....when wireing your
>own toriods, is wire size, and insulation incredibly important?
>It seems like they would be, but a friend of mine said that
>as long as the wire size is close to what it says, than it would
>be fine.

In most cases, the insulation type and wire size are not extremely critical. In some cases they are. If you're filling a toroid with wire, the enamel insulation allows you to get more turns on the core for a given wire size. Wire size is important only for it's current carrying ability. You have to use wire that's heavy enough to carry the design current without excessive I*R losses in the wire. Much more important is the core material. Different core mixes are required for different frequency ranges.

Well, it's not the secret of the year, but it *is* downright
difficult to get one to play with. The local distributors will sell
it at the advertised price only if you want to buy in lots of 100 at a
time. For qty onesies, try about $100+, which puts it slightly above
the price for a whole pcb kit from Elktronics, or the other kit from
Canada.

Here at HP Santa Clara Division, we make an ovenized crystal oscillator (model 10811) which has a tuning diode for electronic fine tuning (there is also a mechanical fine tuning adjustment). The tuning diode is semi-ovenized by proximity to the crystal oven casting and as a result does not contribute significantly to the temperature coefficient of the overall oscillator, which is spec'ed at 2.5 parts in 10^9 over 0 to 70 degrees C. The tuning diode has a tuning range of +/- a part in 10^8.

Also, be sure to read the Motorola Ap. Note about temperature drift of tuning diodes. You can get rid of a lot of it by compensating for the well known 2 mV. per degree C drift of the turn on voltage of a silicon junction diode, as the Ap. Note discusses.

Also, note that some Zener diodes are much quieter than others for biasing tuning diodes. The 10811 oscillator uses a 1N825 Zener, which is very quiet, plus we follow it with an RC filter.

I'm thinking about building the gated noise source in the 1993 ARRL Handbook. It uses a 1N23 for noise, but I haven't seen that diode in catalogs or at the local surplus dealer. (I don't even know whether it's silicon or germanium.) What is a reasonable substitute for the 1N23? I assume I could use any old diode with a poor noise figure?

If you are willing to sacrifice gain, as a first antenna I would suggest a quarter-wave ground-plane. I used brass hobby tubing and rods for the elements because you can get then to telescope into each other to make tuning a breeze. The Ground radials aren't really critical, just cut them to about the right length and solder them to the flange of an SO-239 or a BNC-female chassis connector (much harder). Bend them down at about a 45-degree angle. Solder a 12-inch piece of tubng to the center post and telescope a 12-inch piece of rod into the open end of the tubing. With the antenna well away from nearby objects (preferably WAY up in the air), apply power through a good VHF SWR bridge and adjust the length of the vertical section to minimize SWR at your desired center frequency. Then diddle with the angle of the radials. Keep repeating these steps until you are satisfied that you can't go any lower. Then solder the joint between the tubing and the rod and cover the solder with some heat shrink tubing.

For better mechanical strength, get some PC-7 paste epoxy (or your favorite equivalent) and build a cone of the stuff between the flange and the vertical element. ALLOW THIS TO FULLY CURE BEFORE YOU TUNE THE ANTENNA!!!!!

I wrote a family of cross assemblers and posted them to the
net several years ago. Z8 included.

If you have FTP capability, they are in
/pub/archives/alt.sources/Frankasm on keos.helsinki.fi.

They are also available from the C User's Group (the code library
associated with "The C User's Journal" magazine. You can buy
individual packages on floppy disk, but I recommend you get the
CD-ROM (if you know someone with a drive) from Walnut Creek, the
CD-ROM publisher. This is because several other cross-assembler
packages are in the collection, too. My stuff is "disk" 335, the
Frankenstein Cross Assemblers. For my package, you need a C compiler
and the YACC or Bison parser generator (Disk 285? from the same
library or on one of the Simtel mirror sites).

Tom Bruhns (tomb@lsid.hp.com) (That's me) wrote:
: frequency
: locking is especially easy, since if you assume that the
: VCO won't drift too much in a single count period (say
: 1/10 second), you only have to keep track of the least
: significant bits to get enough info for a correction.

etc.

There has been enough interest in this posted that I wanted to follow up with some observations about the control loop. It's not too hard to get right, but does take some thought. I'm assuming you can find my original article to get the gist of the idea in case you missed it...

Be warned, the following is a bit long.

VCO: You will want a vco that's basically pretty stable, so the correction circuitry won't get fooled, and so you have good short-term performance. This means that it shouldn't jump frequency, at least not very far (50Hz is way more than you'd want to see, even though the controller could correct it), and the drift rate should be reasonable: not exceeding 10Hz/sec would be a decent goal, though you could tolerate quite a bit more. Since the controller only gets a shot at correcting the frequency once per 1/10 second (in this example), you will get all the short-term problems of the vco whistling right through. But it could have a lot of long term drift and you wouldn't care-- too much. You will want a reasonably linear tuning rate, so that the gain of the control loop doesn't change too much as you change frequency. And you do need to characterize the total drift expected, so you can do a decent job in the control loop to accomodate that max change.

VCO control: You should plan to cover the band of interest with a reasonably high change in voltage. This is so that small changes in voltage won't cause as much frequency jump as they would if you were trying to do the control over a very small voltage change. The control voltage reference, as someone else pointed out, should be stable. You can get little reference chips now that should be good for this job: low power and in things like SOT23 cases.

Tuning: I have in mind two rather different ways to accomplish the "analog" tuning. The first uses something like

a 10 turn pot to directly divide down the reference voltage and feed to the VCO control input. If you covered 200kHz, then this would be 20kHz/turn, probably a reasonable tuning rate. If you want, you can have a "fine tweak" single-turn pot added in. In any event, this control voltage will be summed with the locking control voltage--the output of the integrator that accumulates the errors. You can do the summing in an op amp, or just resistively.

Control: I suggested a four-bit counting scheme. The idea is to have two modes: "memorize" and "control." In the memorize mode, the output of the counter is transferred to the latch at the end of each count period. Because the latch contains the same info as the counter, no correction is made. Also during this time, the control integrator is reset to zero with either an FET switch or a mechanical switch. When you switch to "control" (or "lock") mode, the current latch value is held. Then if the counter, at the end of the count period, is different from the latch value, a pulse is integrated onto the control integrator. This is done as a pulse in a small fraction of a second between count periods, so that the VCO frequency will reflect the whole correction during the next count period. You select the integrator gain such that a 7 count error will correct (just under) 70 Hz at the maximum slope of the frequency-vs-control curve of the VCO. So you may only correct 50 Hz, say, at the other end of the VCO control curve where it's less sensitive. But since your correction was saved on an integrator, then the next count period will detect the remaining 20Hz error (plus any additional error) and take most of that out. As you can see, if you change the gain of the system, you can get an exponential decay or a damped "ringing" in toward the right frequency. If you overcorrected too much, you could, of course, get oscillation. You must select the gains correctly. Also, to keep analog noise reasonably low, you may well want an integrator that only can take out, say, 5kHz errors with a 5 volt swing, dividing down its output before sending to the VCO (just part of the resistive summing network with the tuning voltage from the pot). Some notes about what you are correcting: you only get to correct what you count. If the VCO is drifting during the counting, its instantaneous frequency at the end of the count is not what the count tells you it is. So if it's drifting in one direction at a constant rate, for example, you will always be behind in your correction. Those who know control systems will immediately recognize that you can design a control system to keep up exactly with such errors. But--the idea here is to KEEP IT SIMPLE! You could _probably_ do the whole thing in an op amp, a GAL6001, and a colorburst-->60Hz clock divider (like 5 clocks of counting and 1 clock of

integrating), with the usual set of analog parts to match.

More on tuning: I mentioned a second tuning method above. This would eliminate the 10 turn pot. The idea here is to build the control integrator so its output is very stable. You use it to directly control the VCO. Assume 10 volt swing to control 200kHz. That means 50mV/kHz, or 50uV/Hz. The digital control part, then, would integrate only about 500uV/count--you have to be pretty careful about the design here to make sure you didn't get digital noise into the integrator, but it doesn't scare me too much. Now the tuning control would be an input to the integrator: you unlock the loop, and feed a + or - current into the integrator to ramp up or down. You can do this with some fairly simple ckts that will make the tuning rate slow at first and accelerating, so you can get from one end of the band to the other rapidly. As soon as you let go (let's say you have a center-off toggle switch to do this), it goes to lock mode and resets the "rate of tuning" circuit, so you can fairly easily "pulse" the switch to get exactly on. Dunno for sure if this tuning scheme would be acceptable to most users or not: we are so accustomed to direct coupling to a knob. Also, you need something for frequency readout. Maybe one of those National Semiconductor bar graph drivers would do...or a very simple 3.5 digit DVM, with a calibration table (or highly linearized VCO), just monitoring the VCO tuning voltage.

More on control: Since there is an ambiguity of +/- 1/2 count in the counter, it's probably a good idea to not integrate a full correction if you are only one count off the locked count. That is, a 1 count error could be made to integrate only a 3 or 4 Hz correction instead of a full 10Hz. This should be fairly easy to do in the simple "four bit dac" -- 4 resistors -- used in this scheme.

Obviously, if you are comfortable building a VCO with lower guaranteed short term drifts--no jumps and slow thermal drifts--you can make the count period longer and the corrections smaller. This lets you get to finer steps. As Gary C pointed out, the scheme described locks to 10Hz steps, and this may be too coarse for some. Since the circuit will always end up "hunting" around that last 10Hz, it may be unpleasant to listen to, and finer control might be appropriate. It depends a lot on how short-term-stable you can make the VCO.

Final thought (for now ;-) : I suggested a counter, latch and adder(subtracter) as the key digital parts. You can also do this with an up-down counter and a latch: up-count to find the frequency, putting it in the latch. Load the counter with the latch value and down-count during lock.

then the counter value at the end is the correction
(2's complement).

Changes: new mailing lists, .packet rmgroup, and .policy updates

(Note: The following is reprinted with the permission of the author.)

This message describes the rec.radio.amateur.*, rec.radio.cb, rec.radio.info,
and rec.radio.swap newsgroups. It is intended to serve as a guide for the new
reader on what to find where. Questions and comments may be directed to the
author, Jay Maynard, K5ZC, by Internet electronic mail at
jmaynard@oac.hsc.uth.tmc.edu. This message was last changed on 18 September
1993 to add the mailing lists for the new rec.radio.amateur newsgroups, to
note the rmgroup of rec.radio.amateur.packet, and to officially retire some
(in)famous threads of discussion on rec.radio.amateur.policy.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list
for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions
were held on the mailing list, and sent to the mailboxes of those who had
signed up for it. When the Usenet software was created, and net news as we
now know it was developed, a newsgroup was created for hams: net.ham-radio.
The mailing list and the newsgroup were gatewayed together, eventually.

As the net grew, and as packet radio came into vogue, packet discussion began
to dominate other topics in the group and on the list. This resulted in the
logical solution: a group was created to hold the packet discussion, and
another corresponding mailing list was created as well: net.ham-radio.packet
and PACKET-RADIO, respectively.

These two groups served for several years, and went through Usenet's Great
Renaming essentially unchanged, moving from net.ham-radio[.packet] to
rec.ham-radio[.packet]. Readership and volume grew with the rest of the
network.

The INFO-HAMS mailing list was originally run from a US Army computer at
White Sands Missile Range, SIMTEL20. There were few problems with this
arrangement, but one was that the system was not supposed to be used for
commercial purposes. Since one of hams' favorite pastimes is swapping
gear, it was natural for hams to post messages about equipment for sale
to INFO-HAMS/rec.ham-radio. This ran afoul of SIMTEL20's no-commercial-use
restriction, and after some argument, a group was created specifically
```

for messages like that: rec.ham-radio.swap. This group wasn't gatewayed to a mailing list, thus avoiding problems.

While all this was happening, other folks wanted to discuss other aspects of the world of radio than the personal communications services. Those folks created the rec.radio.shortwave and rec.radio.noncomm newsgroups, and established the precedent of the rec.radio.* hierarchy, which in turn reflected Usenet's overall trend toward a hierarchical name structure.

The debate between proponents of a no-code ham radio license and its opponents grew fierce and voluminous in late 1989 and 1990. Eventually, both sides grew weary of the debate, and those who had not been involved even more so. A proposal for a newsgroup dedicated to licensing issues failed. A later proposal was made for a group that would cover the many recurring legal issues discussions. During discussion of the latter proposal, it became clear that it would be desirable to fit the ham radio groups under the rec.radio.* hierarchy. A full-blown reorganization was passed by Usenet voters in January 1991, leading to the overall structure we now use.

After the reorganization, more and more regular information postings began to appear, and were spread out across the various groups in rec.radio.*. Taking the successful example of the news.answers group, where informational postings from across the net are sent, the group rec.radio.info was created in December, 1992, with Mark Salyzyn, VE6MGS, initially serving as moderator.

In January, 1993, many users started complaining about the volume in rec.radio.amateur.misc. This led to a discussion about a second reorganization, which sparked the creation of a mailing list by Ian Kluft, KD6EUI. This list, which was eventually joined by many of the most prolific posters to the ham radio groups, came up with a proposal to add 11 groups to the rec.radio.amateur hierarchy in April 1993. The subsequent vote, held in May and early June, approved the creation of five groups: rec.radio.amateur.digital.misc (to replace .packet), .equipment, .homebrew, .antenna, and .space.

The Current Groups

I can hear you asking, "OK, so this is all neat history, but what does it have to do with me now?" The answer is that the history of each group has a direct bearing on what the group is used for, and what's considered appropriate where.

The easy one is rec.radio.amateur.misc. It is what rec.ham-radio was renamed to during the reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize

this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, should be removed by September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is now rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there.

The first reorganization added two groups to the list, one of which is rec.radio.amateur.policy. This group was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The other added group is rec.radio.cb. This is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently Mark Salyzyn, VE6MGS. The email address for submissions to the group is rec-radio-info@ve6mgs.ampr.ab.ca. Inquires and other administrivia should be directed to rec-radio-request@ve6mgs.ampr.ab.ca. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas,

commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

357. Pkt satellite receiver card for PC?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-15 15:35:50 UTC
From: allenw@bnr.ca
Message-ID: <2jqq4m$9cb@crchh620.bnr.ca>
Source record: 118647
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment

[Q 1]:

I would like to know if there is an ISA-bus card which acts as
a satellite receiver that I can plug into my PC. My "project"
involves a satellite dish with coax cable receiving a packet RF
transmission which I would like to run into my PC for decoding.
The data would then be displayed under Windows3.1/NT/whatever.

[Q 2]:

What are Phil Karn's KA9q C functions?

If my questions don't make sense it's because I'm new to this
and don't know much about packet radio.

Thanks

Allen Willson | BNR claims no reponsiblity

>it's silicon or germanium.) What is a reasonable substitute for the
>1N23? I assume I could use any old diode with a poor noise figure?

The IN23 was a point contact diode used in radar receivers. Similar diodes for this purpose would be 1N21 and 1N21B, or their W or R suffixed equivalents, though the R types are reversed polarity packages so beware. Ordinary diodes can be pressed into service at low frequencies, but won't produce enough broadband noise at higher frequencies to be useful.

An alternative design can use a MRF901 in controlled breakdown mode as a noise source. This can be made to produce robust output up to the gigahertz range. Vacuum tube thermal diodes can also be used as noise sources with broad bandwidths, and regulated heater current can give you a calibrated noise source.

: I am trying to design a regulated 12V power supply ...

: The secondary of the transformer is going to be around 14V 1.5 A, and
: the regulator will be a 7812.

: 1) Have I overlooked anything electrical-wise or safety-wise
: in the circuit? As I said, it's been a couple of years since I
: designed a P.S. and I was going from memory here.

The 7812 needs at least a 3 volt drop (i.e. 15V at the input) for
proper operation. Don't forget to consider the 120-Hz ripple across
the filter capacitors: You need 15V at the bottom of the ripple.
If the ripple is 3V p-p, for example, then you need 16.5V DC minimum
at the input to the regulator.

: 2) What are the values of C1, C2 and C3? (Capacitor type,
: capacitance and voltage ratings)

The capacitor at the output of the regulator is there to improve the
output transient response. A 1 uF tantalum electrolytic would be a
good choice.

The cap at the input is only needed if you have long leads between the
filter capacitor and the regulator.

The filter capacitor size depends on the required ripple voltage.
I use the formula:

$$\text{Peak-to-peak ripple voltage} = \frac{\text{Load current}}{2 * F * C}$$

Where F = 120 Hz and C is the capacitor size. To solve for C, just swap
the position of ripple voltage and C in the formula. The above formula
is actually a bit conservative. However, with high-current, low voltage
supplies, the capacitor series resistance sometimes becomes the limiting
factor for ripple voltage. That's why it can make sense to use more than
one filter cap in parallel to get the required total capacitance.

: 3) Can the 7812 handle 1.5 - 2 A of current? If not, is there
: another fixed 12V regulator I can use (I don't want to use an
: adjustable regulator for reasons of cost and simplicity of
: circuit design)

Not reliably. I generally consider a 78XX to be a 1A device. You can
use two in parallel. If you do that, I suggest including a .1 ohm
(or so) resistor in series with each output to balance the currents.

Be sure to use proper heat sinking. Power dissipation equals load current times (input voltage minus output voltage). If the input is 17V, the output is 12V, and you have a 2A load, that's 10 watts of dissipation, which would require a fair-sized extruded aluminum heat sink.

The 1N23 is a very special diode. Its old like heck, but still
vide used and difficult to find. Try Nebraska Surplus Sales, he
will sell you even one diode.

1N23 is point-contact diode, sensitive to static electricity,
even to RF fields, Vr is something like 5 V or even less. It
goes up to 10 GHz. I have not seen any explanations about the
material, I guess it is silicon diode.

When used as a detector diode, you can replace it with new and
expensive low-barrier Schottky microwave diodes, but as a noise
source I do not know any replacement above 500 MHz. Below that
you can try low capacitance silicon diodes like 1N4148.

Hi,

Has anyone built a ladder filter for SSB using cheap crystals? My Digi-Key catalog has a wide selection from 3.579 MHz to 60 MHz for $1.00 - $1.50 each. How many crystals are needed for 30-40 dB sideband supression? What are the factors in selecting the carrier frequency? If I want a 2.7 KHz bandwidth, does that determine the useable crystal frequency range? Digi-Key sells CTS, Epson, and ECS crystals. Does one brand work best?

Thanks!

Jim

Jim, if you can get access to a late '50s - early 60's ARRL Handbook,
your questions will be answered. I still have a bunch of 455KC (it really
does say KC on them) range crystals that I never did anything with.

It just occurred to me that I could finally get an answer to a question I've wondered about for a long time, namely:

As homebrewers, what test equipment do you use in getting your projects working? Are you using 'scopes, freq. counters, signal generators, sweep generators, GDO's, spectrum analysers? Any other obvious things I've forgotten at 1AM? Comments?

If I get enough responses I'll tabulate them and post them.

Thanks,

Mike, KK6GM

If you are considering building an SSB xtal filter it's well worth looking at the article by W7ZOI on Cohn xtal filters. It appears in 'QRP Classics', and is a reprint from QST. Although I've only built CW filters based on this approach, SSB filters can easily be realised also, and I would think that a filter with 3 or 4 xtals would satisfy your requirement. It probably doesn't matter too much on the make, as long as all the crystals are quite well matched in frequency (to within 10 percent of the filter passband is a good rule).

I use an RF signal generator, Scope, and the most important piece of test
equipment is my commercial receiver. A frequency counter would be nice,
but not necessary, and a spectrum analyzer would be nice, but without the
spectrum analyzer, I use the scope to view the waveform for amplitude and
rough estimate of purity, then the receiver for checking the amplitude of
harmonics. Scope is probably not necessary either if you have an rf voltmeter,
I guess anyway, I never used one, I've always been spoiled with a scope.

RF signal generators for HF show up at the hamfest for basically nothing.

: My questions are:
: 1) Have I overlooked anything electrical-wise or safety-wise
: in the circuit?

I'm curious why the MOV is on the line side of the switch. I'd put it
on the load side so that it wouldn't pop without the device being turned
on. It may save you having to replace it when there was little possibility
of damaging your PS. The addition of a choke in series with the +12
lead going to the HT may help stop RF from getting fed back into the AC
line, causing interference.

: 2) What are the values of C1, C2 and C3? (Capacitor type,
: capacitance and voltage ratings)

For the filter caps I'd suggest electrolytics, with voltage ratings >= 2x the
output voltage of the circuit. As far as value goes, you'll need several
thousand to tens of thousands of uF, depending on load and ripple requirements
of your HT. The ARRL handbook has a section of PS's, and a neat discussion
on calculating ripple.

There is a screw behind the label on the back of the pack, which must
be removed. You will also need to remove the +/- label, and then the
pack will separate at the top, and hinge at the bottom. The only real
difficulty comes when you try to stick the stickers back on.... :-(

If you drop them from high enough, you can break the tabs on them...

From: halbert@world.std.com
Message-ID: <CLCLyJ.A2A@world.std.com>
Source record: 118518

If you want to build your own crystal ladder filters, you may be interested in a spreadsheet I built that performs the calculations in W7ZOI's May 1982 QST article (see below). The spreadsheet can be FTP'd from:

world.std.com: pub/hamradio/ARRL/Server-files/info/qst/xtalf.zip

It's also available from the info@arrl.org mail server, though I forget how that works at the moment. Below is the text explanation included in the .zip file.

As noted below, there is a numerical error in a table in that article. See QST, November 1993, p. 81, Feedback. The spreadsheet has the corrected value.

Regards,
Dan Halbert, KB1RT
halbert@world.std.com
==========
The files in this package are:

XTALF.WK1 (Lotus 1-2-3 spreadsheet)
XTALF.FMT (spreadsheet formatting info)
XTALF.TXT (this file)

Author: Dan Halbert, KB1RT (good in the Callbook).

This package is a Butterworth and Chebyshev crystal ladder filter calculator, done as a Lotus 1-2-3 spreadsheet. This spreadsheet was created on Lotus 1-2-3 Release 4. I have designed it to print on one page when formatted with the given formatting information.

See May 1982 QST, "A unified approach to the design of crystal ladder filters", by Wes Hayward, W7ZOI, p. 21. See also January 1990 QST, "A tester for crystal F, Q, and R", p. 21, by Doug DeMaw, W1FB, which describes a simple test instrument for making the measurements described in the W7ZOI article. Both these articles are reprinted in the ARRL book "W1FB's Design Notebook", by Doug DeMaw.

The spreadsheet is initially loaded with data from the example in that article. The May 1982 QST article has one typo in it, for Butterworth N=4, k_23.

Thanks to all those who've replied to
my posts....

Getting conflicting reports on the wire
for winding coils, though. So, let's
apply this to my "real-life" situation, here.

I'm building a simple (or so I thought)
reciever for 15-Mhz. It calls for a
coil with 26 turns of #24 enamel wire.
I solved on problem, I've found the
enameled wire! YAY! However, our radio
shack only carries size #22 then goes to
#26. No #24 at all, and quote the
salesman, "We don't carry it 'cause
it's, uhhh, to small." Exact quote, no fib!

So, will either of these sizes work, what would
I have to change? Or do I need to find a catalog
for people who carry this?

Thanks for the help!!!!!

The "store bought" plug in adaptors have a nice inductor in series with
the DC supply to the HT. This serves two purposes, it eliminates the
whine of an alternator system, and it stops any spikes from getting to
the HT (When used with a large electrolytic at the HT side).

Made all the difference with my Kenwood TH-77A handheld in the truck.

Date: 1994-02-17 15:41:34 UTC
From: angerhof@bambam.es.com
Message-ID: <2k037e$a1e@orca.es.com>
Source record: 118521

I was recently given an old Motorola car phone, model 1470A. I opened up
the massive electronics box (which weighs about 50 pounds) and found
plug-in units which were labeled something like this: T - 158.520 R - 152.08.
As there were 7 such units, I am guessing there are 7 channels available
for the phone use.

Can this unit be easily adapted to transmit and receive on the 2M band?

Any opinions on this particular model, is it worth the trouble to try the
modifications?

Hi,

I need a simple design for a 20m VFO that drops into the place of a X-tal. My exact transmitting circuit is the 6-watter from the 1986 ARRL Handbook.

I have also built a 40 meter VFO from the QRP tranceiver designs in the 1994 ARRL Handbook and they work. But when I use the VFO with the freq. doubler circuit from the September 1993 issue of CQ, I found the output to be too weak and fundamental frequency rejection is insufficient.

The doubler was originally intended for doubling 3.5 MHz to 7 MHz but I am using it to double 7 MHz to 14 MHz. Is there a problem doing this and/or is there a more suitable means of deriving 20 m from a 40 m VFO?

The VFO works fine right now. I just can't get a strong and clean doubled frequency. Can anyone help me, especially if you have access to the documents I cited, could you take a look at the circuits and advise me. Tks.

385. gasFETs for preamps

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-17 21:51:03 UTC
From: zardoz@ornews.intel.com
Message-ID: <2k0oso$qg3@ornews.intel.com>
Source record: 118525

I finally toasted the gasFET in my old Hamtronics 2 meter preamp somehow.
I called Hamtronics and they said that they are an appliance outlet only now.
What is a good, cheap source for these devices? Mine was supposed to have
been .7 db noise with 13-20 db gain, that's all I know.

Other than soldering them in, what are the hazards once installed? How
much loosely capacitively coupled energy can the gate take? What is the
detrimental effect of installing the preamp inside a rig after a chain of
PIN diodes and other junK? (other than a hacked up rig, of course).
I don't want to mast mount it and I use 75 ohm 3/4" hardline.
Thanks,

I'd recommend moving the MOV to the transformer side of the switch too. Otherwise when you turn off the switch the residual energy in the transformer core may (will sometimes) arc over in your switch. This arc can destroy the switch especially if the transformer is large (lots of stored energy and it has to go somewhere).

I missed the original post on this thread. If not already mentioned, look up also:

"Switchable Bandwidth Crystal Filter" Pivnichny N2DCH
Ham Radio Feb. '90.

and

"Designing and Building Simple Crystal Filters" Hayward W7ZOI
QST July '87.

Some pretty good starting values for the coupling C's are given. My own impirical work confirms the ball-park values for C. For a 1.8kHz band-pass using 4, 4.433, 5, or 6MHz crystals; C's need to be about 33pF. However, at (say) 8MHz, about 220pF C's will be required for a similar band-pass.

I'm not familiar with either the VFO or doubler design, but how about this idea: Build another VFO, but with all the frequency-determining coils and capacitors 1/2 the value. You would end up with a VFO that tunes 14-14.6, assuming the 40 meter version tunes 7-7.3. You could reduce the tuning capacitor size even further (i.e. make it about 1/4 the size instead of 1/2) to reduce the tuning range.

The mysteries of Internet. Your original posting showed up!

About 4 or 5 xtals will be needed to obtain satisfactory sideband rejection. However, not stated in published articles (that I have seen) is the improved sideband rejection obtainable by building your filter into a little in-line compartmented box- made from scraps of circuit board, tin-plate or brass sheet. One xtal and capacitor in each compartment, with a small hole for the connection between.

You must do some math and figure the best IF for the job. Select VFO, carrier (BFO on receive or transceiver) for minimum in-band and nearby spur production (considering harmonics of both oscillators to at least the fifth, and preferably seventh (complex subject)). If you choose a round-numbered IF (most xtals are); then you can simply employ a well-shielded frequency counter (measuring those kHz digits to the right of whole MHz and applying any necessary correction factor for the BFO) for the dial.

The bandwidth(pass) is chiefly determined by the value of coupling capacitor, those that connect each end of the filter, and those to ground at each xtal connection. Increasing C DECREASES the bandwidth. Minimum pass-band ripple is obtained when the input and and output impedances of the filter match the driving and load Z's respectively. However; even with poor matching, the ripple will probably not be too bad, and loss should not be excessive.

The xtals are made cheaply in huge batches, and match each other very closely in frequency. However, when purchasing, make sure that they are

all of the same brand, and do not mix different makes of xtal in any one filter.

: between the pins!)? Can you solder such
: a beast, and how (assuming you don't have
: a reflow oven at home :-)?

You can solder with a fine-tipped iron, a steady hand, and good eyes (or a magnifying glass). Make sure you have some solder-wicking braid on hand for the inevitable solder bridges.

Actually soldering isn't so hard, but unsoldering a multi-pin SMT IC is virtually impossible without special tools. (A heat gun works, but will likely unsolder other nearby components and may scorch the PC board.)

To make the board, I use a laser printer and the special paper sheets designed to iron onto the PC board. You soak the paper off, and the toner remains on the board to act as resist.

I've been told its impossible, and I've been told it will just take a little work. What I'm looking for is a radio (preferably handheld, but mobile would be fine), that can transmit and recieve on VHF lo band and VHF Hi band. While VHF/UHF is common, I was wondering if anyone knew how to modify a radio to do this, or where to get one, or where to look for more info. I ride on several fire departments and ambulances (between home and college), and home operates on Lo-band, and at school, we use Hi-band.

Any suggestions would be appreciated.

Valvo is a subsidiary of Philips (Nederlands). Valvo's headquarters are in
Hamburg. I do not have the exact address here.

Mullard is another Philips subsidiary based on UK. Usualy you can get most
of the products of the one company by the other one.

That is a solution, but does not take into account how the transistor acts
versus the frequency.
The idea behind a frequency multiplier is the same as a class C amplifier.
I mean, you take the output from the VCO, and feed it into a small-signal
class C (typically a transistor with emm. grounded, or better a FET, because
FET are known to show only quadratic behaviour), whose output is connected to
a parallel LC network (or ceramic filter, or whatever) tuned at the second
harmonic. That should give you a neat output.

I'm a self-confessed test-equipment-aholic.

Rarely on the air, usually fixing something for someone, or
developing something.....

Meter... I only use this as an ohmmeter/continuity tester, I rarely
need precision in measuring a voltage, I use a DC coupled scope instead as
any AC components and turn on/off transients can be seen.

Scope... my prime piece of test equipment. 50 MHz bandwidth seems OK,
but occasionally would like more (I use surplus HP 180 series)

Sig Gen... quite essential, you need to cover the bands of interest
and receiver IFs. AM is not so important, I use FM often. Good screening
and a good attenuator to allow you to go down to 0.1 uV is very
important. I have a surplus Marconi 2008 that the Brit army didn't hurt
too much, 10 kHz - 512 MHz with ability to sweep, lab quality, bought
dirt cheap non-working... just dial cord stuck ! :-) :-)

Power attenuator... Most essential, to allow use of test gear on TX
output without severe risk of damage, used with counter, power meter
and spectrum analyser, occasionally with scope to watch keying envelope.

GDO Have one, but can't remember using it in shack, not enough freq
precision for tuning antennas, maybe I'd do better with something with a
built-in counter ?

Counter, needs coverage to highest band of interest, and possibly to
highest freq oscillator you have.

Power meter... Found set of heads for precision RF power meter on
junk stall at rally for 50 pence, now accompanied by surplus meter. Nice
to have something accurate, but accuracy is not so important, diode
detector and power atenuator/dummy load is OK if it covers all bands of
interest.

Spectrum analyser... I know a few keen constructors who now sport
real ones bought surplus, and several who have built cable tuner based
units. You need to cover the 3rd harmonic of the highest band of
interest, but also coverage is important to about 1GHz to cover the
region of most spurious oscillations. Connect a length of coax to the
input and make a 20mm loop at the far end and you have the ultimate
trouble sniffer and tank peaker. Surplus prices for a commercial lab
grade unit hover around the bottom end of the new HF transceiver price
range, I went for a dead unit and fixed it... much cheaper as few dare
attempt such a repair job. Ironically it is easier than people think.
These machines make life easier, faster, and more easily understood.

Worth keeping a look out for a bargain. 1960s and early 1970s HP and Tek units are appearing in increasing quantities on the surplus market, so they are not as exotic as you might think.

LCR bridge... something to check capacitors is important, especially with the poor and confusing markings on many parts, is important. I'm just plain jammy, I walked into a surplus trader's place and there was a Wayne-Kerr standards lab type unit, they didn't know what it was, had priced it for what they thought the case, knobs, psu were worth, and I walked out with it for 45 pounds, it proved to be fully working.

Big box of cables and adaptors... just try doing without one.

TDR (Time Domain Reflectometer) Well, it was on this stall at a rally, and the bloke wanted 35 pounds, it proved 100% working when I got it home. This device is best described as an in-cable radar set, used to test transmission lines and connectors. It fires a pulse down the line and plots a trace of reflection voltage versus time so you can measure exactly how bad a mismatch is, and measure just how far down the line it is. It's nice to know I've got one, should I ever need it, but I must confess I've not (yet) used it in anger. The name alone frightens people, they seem to always be sold at "for the parts" prices. If people stick pins in your co-ax, then you NEED one of these...

Soldering iron... goes without saying, but thermostatic ones are addictive.

I don't have a transistor tester, it's usually clear enough after a look with the scope whether a device is worth changing. If it takes more finding then it is unlikely that a transistor tester would have found it.

Tube testers don't test transmitting tubes, and other tubes are becoming rare. If you use tubed receivers etc, then a tester is a good idea.

Receivers... very useful, to check modulation and as a more sensitive spurious/harmonic hunter than an absorption wavemeter.

Absorption wavemeter... brit licence requires me to have one and be able to use it. Just sits on the shelf. Cannot be sensitive enough to find spurii still big enough to cause trouble, but if you don't have a spectrum analyser, or high quality wide range receiver it is all that's available...

Pillar drill... makes metal bashing easier

Lathe... don't neglect the mechanical aspects, this fellow has paid for itself in fixed rotators. Allows me to attempt electro mechanical projects like wide spaced capacitors and motor drives.

****

A long list, extreme, perhaps for an amateur shack ?

The whole lot cost less than a middle-of-the-range new HF transceiver, because I did not go out shopping, but just kept my eyes open and snapped up bargains as they appeared. I learned a lot from the bits that needed fixing.

Both my typing fingers hurt,

David GM4ZNX

73 de 9V Daniel

I do not have the circuit mentioned in 93 issue of CQ available to me. However, I have used other circuits to great success. Both may be found in Solid State Design by Hayward and DeMaw. One is a broadband diode doubler that is extremely simple and works at any hf frequency. However, it does require a fair amount of drive. (about +10dBm? can't remember) Even with randomly chosen diodes in the doubler, I have seen 30+ dB rejection of the driving waveform.

The other doubler is very similiar, but uses transistors instead of diodes. It also requires plenty of drive unless the transistors are biased on slightly. Then it is easy to drive. 0 dBm will drive it just fine. It also has good rejection of driving waveform. If you use dual transistors or at least two transistors on a single die (eg CA3028, or CA3049T) even greater driving waveform rejection can be had. Last night I saw about 45dB rejection of a 7MHz driving source while doubling to 14 MHz.

The transistor type doublers are usually shown with a resonant tank circuit in the collector circuit tuned to the 2x frequency. However I have found that the same circuit can operate well at a broadband doubler by substituiting a 50uH choke in the collector circuit. You must however at some point filter out all the harmonics except for the second. A great advantage of this circuit is that the odd harmonics are greatly suppressed thus there are 2 octaves of bandwidth between even harmonics which relaxes filering requirments.

Hope this helps. Oh yeah, also see: Accessories for your VFO, Jan 1988, QST.

Best wishes,

Roger Traylor

Aside from my trusty Simpson 260, the most valuable piece of test
equipment I have is my IFR station monitor. It's several instruments
rolled into one. I also use a 4 ch 250 MHz Tek scope, an old Tek 491
10 MHz-40 GHz lab type spectrum analyzer, and of course a Bird wattmeter.
I also find a good step attenuator very handy.

Though I have a frequency counter (two in fact), I find I almost never
use them since the IFR can give me that information. I have four signal
generators, but the IFR duplicates the range of two of them, up to 1 GHz,
so those rarely see use. I've got a function generator that's used
ocasionally, but the IFR has that built in too. I do sweeping with my
Science Workshop spectrum analyzer with tracking generator. A newer
IFR would have that built in too. I think you can gather that I like
the IFR by now. :-)

But the best piece of test equipment is between my ears, a little bit
of common sense, and a whole lot of experience.

All of the above and herds more. Most hams are not 'fortunate' enough
to repair and calibrate HP instruments for a living, though.

Your test equipment needs depend on your homebrew projects. For t-shooting
a pumpkin-light-flasher for halloween, a DVM would be enough. For trying
to get your 60 Ghz receiver (we do have a band up there somewhere?) working,
you'll need more equipment. Most 'common' stuff can be fixed with O'scope,
DVM, a signal source in the area of interest (borrow your buddies HT), a
receiver in the......(buddies HT again), and a couple of variable power
supplies. A small one, and big one for when you want to really weld something.

If you do lots of digital stuff, a signal injector or function generator,
and a signal tracer would be nice.

Maybe its been overlooked, but good tools, soldering iron, third hand,
work space, safety equipment, anti-static stuff, lighting, cables, test
leads, etc. all can turn a bench project into something enjoyable rather
than a chore.

Before I got divorced, a couple of the tools I valued most were my two
mechanical quality inspectors, ages less than 10. Except for dangerous
voltages and tools, these two made the whole project more interesting.
Parts all over the place. What I'm saying here is: by sharing a project
with say, another ham (with HT), you both can use your heads to complete
a project. Maybe a little off track here, but it takes anothers extra
motivation to bench race electrons at home after doing it at work all day!
You both learn and enjoy the project.

What is your next project, Mike?

Like the gentleman from Scotland, I too spend most of my time on the bench.

I own and can recommend these kinds of instruments:

DMM --Absolutely essential. Until I fried my handheld unit, I was also
using it for continuity tests. The Radio Shack models are OK.
If you have the room for a bench meter, look for the HP 3440 DMM with
plug-ins; it's an excellent value; I've found them for $10 or so at
the fleas, and they are wonderful!

That being said, *the* most used instrument on my bench is a continuity
tester that beeps according to the resistance across its leads; it was
a $2 special at Radio Shack and definitely the best $2 I spent. One
could do the same with a 555 and a few other parts.

Scope--Buy Tektronix. Period. I've owned three 500-series Tek scopes and
all of them have worked and even been in calibration! I'm using a 545
(30 MHz BW) presently.

Frequency counter, signal generator--I've a Systron/Donner counter that
doesn't work (yet!) and a Hickok 277 signal generator that does. The latter
is very useful and will be even more so once I get the counter working.

A word on broken test equipment at fleas: If the instrument is in otherwise
good shape (i.e. not crushed, CRT not busted), and it's offered at a cheap
price, don't be afraid to buy it. That's how I got most of my gear!
At worst, you can strip them for parts, perhaps even buying several units
to make up one good instrument. I love doing this sort of stuff, and I
get to learn something besides!

Other stuff--I've a HV probe (for TV servicing that I sometimes do); this
isn't as useful to the average ham. I do have a transistor tester, though
I superseded it with a signature analysis box hooked up to the scope.
If you do digital work (myself, very occasionally), you might want a logic
probe and pulser (I haven't used mine for years, but then again, tomorrow
I might need it. :))

: $1.00 - $1.50 each. How many crystals are needed for 30-40 dB sideband
: supression?

I have built CW filters, but not SSB filters. I found that my filter with
4 crystals gave better ultimate rejection (far from the center frequency)
than the 8-pole filter that came with the radio. Ultimate rejection is more
a function of shielding and grounding (to avoid leakage around the filter)
than of the number of crystals.

That may not answer your question, however, since sideband suppression
requires close-in rejection. I still bet you could get 30-40 dB with
4 poles.

Hi,

I'd like to know what considerations are required to modify an existing HF RF Power stage to a higher power without needing
to actually build a separate HF linear amp. Specifically I'd like to know if it is possible to drop a different transistor into
place and change the current limiting resistor of the final stage, provided the transistor is carefully selected, and get an
increased power output? What about the driver stage? Is the output of the driver stage critical as I see in the catalog, it appears
that some of these transistors come with a specified input power, eg: 0.1 watt in/ 15 watt out/ Ppe 23 dB. What exactly is the Ppe?
Another thing about transistor selection, will a VHF transistor work well in a HF circuit? For example, the specs above are for the
MRF 261 transistor which is actually a VHF transistor, will this work in a HF power stage then? More specifically I am trying to
modify the output of the ARK 20 QRP transceiver from about 3 watts to say 12-20 watts or so. How difficult will the change in
design be? The reason I am thinking of this is that I want to keep the QSK active rather than have a separate QSK TR switch for the
additional linear amp.

Tks for any advice.

Not only that, but you can get a plug-on module that lets the
54600/1 behave as a spectrum analyzer. Works best on steady-state
signals, but I've found it useful up through the tens of MHz range.
It's great for tweaking audio stuff.

For most lower frequency (<100MHz) stuff, it does a pretty good job
of measuring frequency, voltages, etc. I don't even own a good
multimeter but have been able to build and debug a few advanced
projects using the scope instead. And when you get bored it will
play Tetris! :-)

Basic, basic here -- a scope (old tube Tek 533A), old Triplett FETVOM,
cheap digital multimeter I got for 4 bucks that had one resistor bad, an
old Eico grid-dip meter in poor shape.

and, of course, my Mac -- to access these groups, and to use my
spreadsheet full of formulas to calculate dBm, turns on toroids, etc.

That the radio has Channel Elements that are labeled for Transmit
and Receive says that it may well be worth the effort. Some models
for IMTS service used a single channel element for the transmit
freq the first IF was the same as the repeater split.

First is this a tube radio? If so, then it may well be of the
U43GGT vintage. If its solid state receive and tube transmit,
then its proly U43HHT.

Take a look at the labeling and see if it has an identifier
similar to those U = Universal, T = Trunk, F = Front mount
#1 = power, #2 = band, Receive.model, Transmit.model, Power.type
and then a string of four numbers for more info on the details
of the radio. As a full listing from a Mocom-70 (first radio
that I could grab...), its a T44BBA3000A SP1.
Oops. I forgot to mention that they sometimes stick another
rev designator (the A in 3000A) in. The SP means that its
SPecial somehow and SP1 means that its the first special hack.

SP means also that you need to keep your eyes open for
things that are different... somehow. Most often, these
are only modest problems... but some take some real.head.scratchin
to figure out and un-hack.

I didn't use this on my HT (or any of my ham rigs, better filtering I guess), but I had a portable stereo that I used the car battery to power. I had a real problem with alternator whine in the system. I found an old AM radio in the GoodWill store (I am amazed at what you can find to kludge parts from), and took the ferrite looopstick antenna out of it. Wrap as much wire as you can around it, (I used 14 gauge), and put SuperGlue over all the wraps. Makes a fairly high-power inductor. I have no idea what the inductance is, but after installing it in-line with the power lead, my o'scope didn't even show a ripple when I started the car....

Maybe that will help...I didn't put a cap in with it, I meant to, but was too pleased with the results I had....

413. JFET VFOs -- Diode needed?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-19 22:51:40 UTC
From: mjsilva@ted.win.NET
Message-ID: <65@ted.win.net>
Source record: 118553

In the Febuary 1994 issue of QEX in an article on oscillator phase noise it is stated that the diode commonly placed between the gate of a JFET VFO and ground degrades the noise performance of the oscillator and does not improve the long-term stability. Any info or opinions on this?

Daniel: here's a reprint of the second project I posted on .homebrew.

Jeff NH6IL

****
Subject: Project 2 - 20 meter QRP CW xmtr

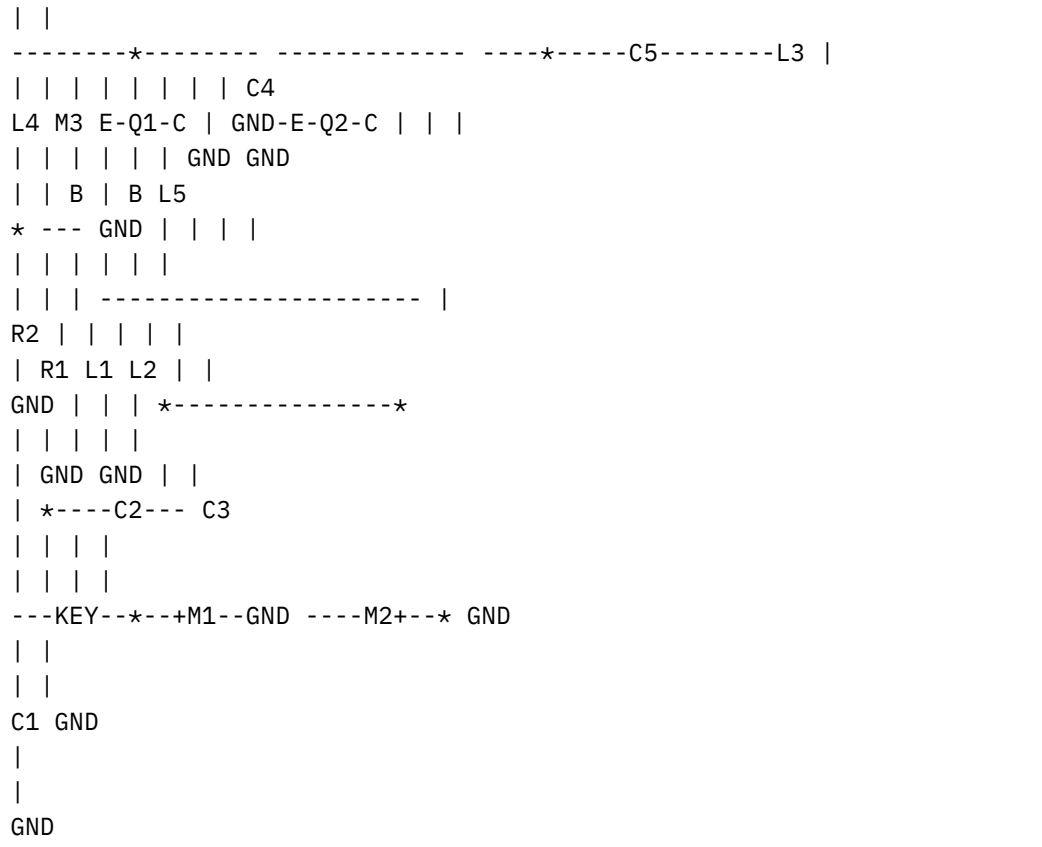
Here's the second QRP project taken from 101 EASY HAM RADIO PROJECTS,
by Robert Brown and Tom Kneitel; again, since the book is out of print,
I assume there will be no copyright problems...
This project is a simple 20 meter CW xmtr with output about 100 mw (?).
Here are the authors' comments:
"If you have always wanted to try low-power on 20 meters, here is an
excellent method for joining the growing ranks of flea-power addicts -
and doing it inexpensively. This circuit is capable of world-wide QSO's,
given the right conditions and assuming QRM is not present.
"The transmitter uses a pair of GE-1 universal replacement transistors
in a unique circuit configuration a great more sophisticated than you
would normally expect for an under-one-watt rig. Crystal can be a
fundamental 14-mHz type.
"L1 should be adjusted for sure-fire oscillation every time the
key is depressed. C4 is simply adjusted for maximum output on the FSM."

PARTS LIST:

C1, C2 .02 uF capacitors
C3, C5 .002 uF capacitors
C4 51 pF variable capacitor
L1 38 turns of No. 22 enameled wire on a 1/2 in. diameter
slug-tuned form
L2 8 turns of No. 22 enameled wire wound over cold end of L1
L3 Coil, 17 turns of Air Dux 616T (or equiv.) tapped 5 1/2
turns from cold end
L4, L5 2.5 mH rf choke (National R-100 or equiv.)
M1 1.5 volt dry cell

M2 6 volt battery
M3 14 mHz crystal
Q1, Q2 GE-1 transistors
R1 180 ohm resistor
R2 1.1 megohm resistor

As before, rather than trying to `draw' the symbol for each component, I've just inserted the part number. Oh, note the polarities of the batteries M1 and M2. GND = ground, ANT = antenna, E = emittor, ANT C = collector, B = base, KEY = well, this is a CW rig.... |



Note that the collector of Q1 `jumps' over the hot end of L2; this is the only jump. * = a junction of 3 or more leads.

.... .- ...- . ..-. ..- -. !

>FSRLA@Aurora.alaska.edu

The inductance of a coil is a function of its length and
cross-section area for a constant number of turns.

If you keep the legth of the coil the same, then there will
be no impact on the impeadance by using wire that is two
wire-sizes smaller. There will be some small reduction in
its Q from the slightly higher resistance.

Use this *now* David. Take scope pictures of all your antennas while they're working. You can then pulse the line anytime you wonder if something has gone sour. If the traces don't match, it has. Otherwise you've saved yourself a trip up the tower.

>and reception?

A balun's purpose is to transform an unbalanced feed to a balanced load,
or vice versa. What it really buys you is keeping RF current off the shield
of coaxial feeders. This can distort your antenna pattern because the shield
of the coax acts as an additional unwanted radiating element.

How to test. You need a "sniffer" to detect currents on the outside of
the coax shield. A simple sniffer is a loop of wire soldered to a pilot
lamp. While transmitting, run the loop up and down the coax (loop plane
parallel to the coax). If the bulb lights, the balun isn't doing it's
job. You can make this more sensitive by using a loop tuned to the
transmitter frequency (series resonant). Electrically shielding the loop
will allow it to respond only to the H field from the coax.

In most cases, with simple dipoles, a balun is a waste of time and
money. Sometimes it helps, but those cases are so installation dependent
that on the air testing is the only real way to determine if it's doing
you any good. (Radiation from the coax can sometimes be *helpful* in
making contacts under certain conditions, like when the other station
is off the end of your dipole.)

419. Advice, please, re 12V Battery Supply in Shack

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-21 00:51:26 UTC
From: emd@ham.almanac.bc.ca
Message-ID: <F9N3Hc1w165w@ham.almanac.bc.ca>
Source record: 118559

I'm planning to resurrect my ham shack this spring (other projects and illness have delayed it).

I have a number of items in the shack I want to power off a 12 V battery - including a VHF 10 W radio, a UHF 10 W radio, a small 12 V TV, a packet TNC and a desk lamp.

A separate 12 V battery will supply power to a TS-820S as backup for power failure, which happens fairly often around here. (Using the same battery for both purposes is out, as the 820 DC power supply puts a heavy ripple on the battery when in use).

The question is the best way to keep the battery adequately charged without over-charging it - I'm not sure merely connecting a DC power supply to the battery is a very good answer.

Suggestions as to the best method to both power the equipment AND keep the battery from deteriorating would be appreciated.

This whole subject was very well covered in a series of
articles in that evil cultist rag QST.

See "Practical Battery-Back-Up Power fro Amateur Radio
Stations - Part 1, 2, 3." March, April, May 1990.

Brian Kantor posted a good writeup on lead acid batteries on 28 May
1992. I have a copy and will mail it to the original poster or anyone
else who wants a copy.

I assume you made the balun by wrapping your coax a number of times
through the toroid core. You would get some balun action even if the
core had no magnetic properties whatever. In fact, some people
habitually make "air baluns" by simply winding several turns of coax
in a loop. I wouldn't worry too much about it -- it can't hurt and
it probably is giving you at least some balun action.

A very, very sound suggestion, but I'm in one of those ALL external antennae banned areas. My HF doublet is on a halliard, and the 2m thing is in the attic. I can get at all of them in under 2 minutes. The guys with the big rotating towers and the stacked monobanders *really* need a TDR.

Nice for checking cables, even if there is a corroded region away from the ends, this thing will spot them and measure their location.

Cheers
David

Great idea. Anyone who wishes that they had such a piece of equipment can build one for next to nothing. The ARRL handbook page 27-31 (year 199?) has a great little circuit that works very well. One drawback is that for it too be useful for the lengths of coax that amateurs usually use (i.e. around 50ft) then you NEED a scope with a bandwidth of 50MHz or more.
Enjoy

: I know they're not strictly 8-bit processors, but have you considered
: doing flavours of frankasm for the Microchip PICs ?

Another of the C Users Group did one for the PIC1650. At the time
I did most of this, the PIC's were just another strange chip from the
microprocessor equivalent of the Precambrian era. I'm also not sure
that Intel Hex is the best output file format, and would cause a lot
of confusion for the users. And supporting a new output format would
mean a seperate version of the common code. No big deal as far as
how much time it would take, but the PIC's just don't fit in to the existing
assemblers. (Read this as: I coded myself into a corner ;-)).

Here's a list of the older cross-assemblers in the CUG library. This
is a couple of years old, but the newer additions are in the ad in
the C User's Journal magazine.

Circuit Cellar Ink had a TDR project about a year ago. It was very
clever, using an 8051 and an LCD display. I don't think it provided
the full graph that a nice TDR provides. That means it couldn't give
you a picture of _all_ discontinuities.

No, actually I made the balun my making something like 4 or 5 bifilar turns
on a toroid originally used for power line filtering. What do you think of
this?

Does anyone out there know the part number of the high-current version of the 7812? Or, alternatively, can someone suggest a similar part I can use? I am building a P.S. that will need to drop 14.8V down to 12V at around 4 A. The Radio Shack salesdroid I asked did not list anything in their database.

Alternately, since I know the standard (TO-220) 7812 can handle up to about 1.5A, would putting, say, 4 of them in parallel work?

Thanks.

I just obtained a pot full of 1N4007 diodes. They are 1KV @ 1A. I plan on using many of them for a bridge for a HV power supply. Since the supply is going to put out somewhere around 4KV, I will want to series a number of these guys to get enough piv for (since I am very conservative) around 8KV. Since they are rated at 1A, I am thinking that I want to parallel a few of these to get a good 3A rating. Anyboday see any problem with paralleling 3 of these diodes? I realize that the forward resistance may be different for them.

I would use coax. That way you are guaranteed a continuous 50-ohm
transmission line. (The two wires likely are not 50-ohm impedance.)
If the toroid doesn't work, then you are no worse off than if you had
just connected the coax directly to the antenna.

Does anybody have plans for a DIY audio notch filter ?
Am I looking to build one that has both variable centre
frequency and bandwidth.

MFJ sell a unit that is just what I am looking for,
but the price is more than I am will to pay. In their
unit you can adjust both centre frequency and bandwidth
independently.

I have found a circuit that uses an OP-amp and three
resistors. The problem is that it is not possible to
vary the bandwith / centre frequency with out messing
up the other or the gain. I suppose this circuit may
work but it would not be very useable.

I am not a elecronics wiz but I have built circuits
in the past, so I am not afraid to give this a try.

thanks, Harland

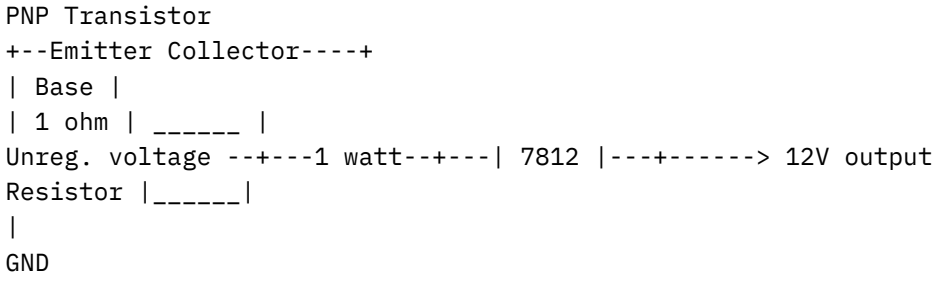
Yes you can parallel them. I'd put a 0.1 ohm resistor in series with
each output to make sure they share the load fairly equally.

Another trick is to add a power transistor:



The 7812 only has to put out about .6A, the PNP power transistor
handles the rest. Don't forget the standard protection diode
from output (anode) to input (cathode).

Wow, 3A at 4KV! And you're not even from California :=)

If all the diodes are from the same production lot, they should be
well-matched. Or you could run about 1/2 amp through each one and measure
the forward voltage and parallel them in matched sets. Unfortunately, as
one diode in the parallel group heats up, its forward voltage drops so
it sucks more current, so it heats up more, so... blam!

If you parallel diodes, be sure they are well-coupled thermally: Solder
them to a PC board with a pair of short, very fat traces connecting the
parallel diodes. I wouldn't count on 3A with 3 diodes using that technique,
but you should get something better than 1A.

What are the advantages/disadvantages of RF power MOSFET's? From what the listing shows, they have more gain than bipolars. Are there any "gotchyas"? How does efficiency compare? They are listed for 28 or 50 volt supplies. How much power can you get at 12 volts? The 1994 ARRL handbook doesn't seem to cover any of this.

Using pulse generators with scopes, or the published DIY versions is all OK, but the thing I got has over 1 GHz of bandwidth, and can discriminate very small distances (millimetre). At 35 quid it was cheaper than you would likely find either a scope or a pulse gen at a rally or at a surplus store.

I've also got most (but not all) of a 12 GHz combined sampling scope and TDR, but see no real use in the shack for it. Bought a scope frame with this plugged into it, for less than the going rate for the frame alone. TDRs really seem to confuse people... maybe the seller didn't realise the frame was more useful and valuable than the plug-in?

I use TDRs professionally to debug mismatches etc, and to develop broadband transformers (there is rather a good set of HP applications notes...) but nowadays I more often use a network analyser with a mathematically computed TDR function when I'd like to see the time response rather than mag&phase versus freq.

Everyone seems to know the TEK scope families around here, but no-one seems to know the old HP180 family, so I keep picking up odd bits at absolute bargain prices, and I have a bit of an inside track on knowing my way around them. Typically a 50MHz dual trace dual timebase with a reasonably bright CRT capable of very fine focus for under $100 ! The only problem is that the trigger circuit requires canny adjustment to get it to work at its best.

Cheers
David

448. How to measure low power @ VHF & above.

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-23 17:41:40 UTC

Anyone have any favourite methods for measuring VHF/UHF
power in the 1 - 10 mW range ? I can't just go out and
buy a bolometer, so what do people suggest ?

FWIW, I have two immediate applications, one is connecting
a transverter to a TS-711A, the other is measuring the output
power of a small UHF oscillator & amplifier.

I have a spectrum analyser, but it's not directly calibrated, I
can measure differences using the IF attenuator, though..

: : ARRL handbook doesn't seem to cover any of this.

: Well. The first advantage of a MOSFET is its high input impedance.

That's true at low frequencies, but power MOSFETs have high input
capacitance, so the impedance is actually quite low at VHF frequencies.

: It doesn't really sucks much power from the previous stage.

Again, that's true at low frequencies, but not so true at VHF. Even if
you can tune out the input capacitance, it is hard to do that without
losses in the matching network, not to mention that the FET input
impedance becomes lossy at those frequencies.

: Their input
: impedance is essentially capacitive. They are more stable than bipolar.
: They exhibit only quadratic distorsion, thus a push pull stage made up
: with MOSFET can be really linear.

They are quadratic only when operated in the "linear" region (class A).
As soon as you bias them into class AB or beyond, they have lots of
odd-order distortion. Hi-fi amplifiers can afford to waste power
with class-A operation in order to get low distortion, but you generally
don't want (or need) to do that with an RF amp.

: MOSFET also tend to dissipate less power than BJT, and to have a higher
: bandwidth. Their output impedance varies less with frequency.

What is true of MOSFETs is that they don't have the secondary breakdown
problem of bipolars, so it's easier to avoid blowing them up.
Also they are easier to run in parallel, since the on-resistance has
a positive temperature characteristic (opposite of the saturation
voltage of bipolars.) And of course, at lower frequencies (HF range)
they really do take less drive power if tuned properly.

There is a well-known form of oscillation that can take place when
power MOSFET's are paralleled. Be sure to install ferrite beads on
the gate leads to avoid this problem.

452. Forming inductors out of PCB traces question

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-24 02:02:29 UTC
From: jdc3538@ultb.isc.rit.edu
Message-ID: <1994Feb24.020229.619@ultb.isc.rit.edu>
Source record: 118492
Cross-posted to: sci.electronics,rec.radio.amateur.homebrew

I once saw a RF modulator that used PC board traces for the inductor
in its tuned circuit; they were in a spiral pattern. Is this a good
method for forming inductors? Does capacitance to a ground plane
layer mess things up? I'd like to form a lowpass filter, so stray
capacitance to ground may not be a really bad thing..

Also, how does one compute inductance? The ARRL Handbook gives a
formula for inductance of a coil where (coil length) > (.4 * coil diameter).
In this case we are working in a flat plane, so coil length = 0.
Also, coil diameter is not constant with a spiral inductor.

Any suggestions, ideas or references to books/articles are appreciated.

I've seen guys try the battery chargers that are supposed to monitor the battery voltage and stop charging when the voltage gets to a certain point. These chargers are for batteries in boats, etc. It seems that just don't work. So I took a lamp timer and plugged the charger into it, and set it for four or six hours. It reduces the charger's tendency to overcharge. If the battery gets a little on the low voltage side, just add a few hours to the charging time. The other thing I would consider is swapping the battery periodically with one in an auto.

Open up an IBM PC power supply, and you'll find a couple small chokes wound around ferrite rods. The material used is optimized for the 100 KHz region and tends to be a bit lossy at HF, but it's okay.

On top of this, you get some nice film capacitors, a bunch of electrolytics, some good switching transistors, and two 200V electrolytics with very large values.

Your local PC repair place is probably throwing several power supplies in the trash, because they aren't worth the money to repair when they fail. Absolute parts goldmines.

The lowball method I use is a calibrated Schottkey diode detector.
See my HR Mag microwave station design series from 1988 for a circuit
and calibration curve; June '88 (Page 23). While it works at the levels you
mention, this method is limited in range and suffers from error if the
signal is not sinusoidal (large harmonic content, for example).
If your analyzer is functional and only uncalibrated, it is no doubt very
worthwhile to get it going since it offers a lot more information beyond
power. If +-1 dB sort of accuracy isn't enough for you, you might
consider building your own power meter. There's an interesting construction
article in Dececmber 1977 HR Mag (page 38) by WA4ZRP. He uses small (grain
of wheat size) lamps and seems to get reasonable performance to 500 MHz.

You can probably buy the crystal sockets from Petersen Radio. I've gotten HC-6 sockets from them in the past. They advertise in the back of QST and have responded very quickly to every order I've placed with them. 712-323-7539.

For a low cost fm reciver a Signetics 604 looks very good over the same range uisng 4 resistors, 8 capacitors, 1 tank curcuit and a ceramic IF filter and has audio and data outputs. It would also need a couple of stages of audio gain. As I recall the chip is also in the $5.00 range.

461. My List of Mail Order Electronics Companies

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-25 16:44:07 UTC
From: jfw@ksr.com
Message-ID: <2kl9sn$opl@hopscotch.ksr.com>
Source record: 118506
Cross-posted to: sci.electronics,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.info

A real prompt update for once; check the end for the changes (as usual).

[$Revision: 2.16 $; last updated Feb 25, 1994]

Here is my list of companies which will sell electronic components in
small quantities. Most of these places I have bought from, a couple
I haven't. Being a ham radio operator, I am most interested in
RF components, and in particular, air variable capacitors, which tend to be
scarce (and tend to be used or surplus even if I've otherwise labelled the
seller as "NEW"). I apologize in advance for disparaging remarks about
what happens when parts suppliers start selling computers, but anyone who
has watched Jameco over the years will know just what I mean (though
their latest catalog hints at possibly returning to selling parts).

Categories are:
NEW COMPONENTS Distributors and sellers of new components, or "new and some
used" in a couple of cases.
SURPLUS ELECTRONICS Usually overstocks, occasionally used equipment.
Ideal for stocking the junkbox, usually have dependable stock lines
of resistors, capacitors, and some semiconductors, but won't have
those LCD modules forever... An invaluable resource, don't shy away
from them.
SPECIALTY COMPONENTS In particular, crystals and toroidal cores.
KITS Ham radio kits, random electronic kits, whatever they have.
LITTLE GUYS Separated out because of some twisted sentimentality,
I suppose. Intended to honor one or two ham spare-bedroom
operations. Note that sending $1 along with catalog requests
is a big help for these folks.
PUBLICATIONS Two publications which are essentially all want-ads, plus
the address for SAMS PHOTOFACTS because everyone always asks about
it on sci.electronics.

Note on shipping costs: I don't always update these frequently enough, and
they're generally for continental US unless otherwise mentioned.

NEW COMPONENTS:

Ocean State Electronics
P.O. Box 1458
Westerly RI 02891
+1-800-866-6626 (orders)
+1-401-596-3080
+1-401-596-3590 (FAX)
Minimum $5, S&H $4, free catalog. Wide array of RF parts, especially
air variables and B&W coils.

Radiokit (store is located at:)
P.O.Box 973 169 Jeremy Hill Rd.
Pelham NH 03076 Pelham NH 03076
+1-603-635-2235
+1-603-635-2943 (FAX)
No minimum ($3 service charge if under $20), many kits, lots of J. W. Miller chokes & coils, B&W coils, RF switches, Millen variable capacitors, lots of parts in general. As of 24-Feb-94, they are again STILL out of catalogs, and just barely might have one by Dayton this year. They do accept mail orders, but you'll have to call for prices and availability. A classified ad in 3/94 QST says "Call/SASE", I guess they may have fliers.

Circuit Specialists Inc
P. O. Box 3047
Scottsdale AZ 85271-3047
+1-800-528-1417
No minimum with check or money order, $15 otherwise. $3 S&H.
New electronics, good RF assortment, increasing infestation of computers.

Mouser Electronics Mouser Electronics Mouser Electronics
11433 Woodside Ave. 2401 Highway 287 North 12 Emery Ave.
Santee CA 92071 Mansfield TX 76063 Randolf NJ 07869
Mouser Electronics
370 Tomkins Court
Gilroy CA 95020
Catalog Subscriptions: (800) 992-9943 (Continental US only)
Sales & Service: (800) 34-MOUSER (800-346-6873) (US, Puerto R., Canada)
Very complete catalog of brand-new components (though no air variables). Usually quick service, $20 "minimum" ($5 charge under $20). When ordering, you may want to be sure to ask about availability and shipping locations; they have several warehouses, and frequently orders will get sent from several warehouses (which drives up the shipping costs). Export orders have a $100 minimum, except for Canada and Mexico.

Digi-Key
701 Brooks Ave. South
P.O.Box 677
Thief River Falls, MN 56701-0677
+1-800-DIGI-KEY (334-4539)
+1-218-681-3380 (FAX)
No minimum, $5 handling under $25, free and very complete catalog, very nice indeed. Prices aren't always the best, but rarely excessive. Weak on RF specialty parts (though they now have the ever-popular NE602N), but they do have blue LEDs.

Active Electronics
11 Cummings Park 237 Hymus Blvd
Woburn MA 01801 Pointe Claire, Quebec, H9R 5C7
+1-800-677-8899 (Main number for US and Canada)
+1-514-630-7410 (International)
+1-514-697-8112 (FAX)
$25 minimum, $5 S&H UPS, catalog has a "$10 Suggested retail price" but they

sent mine for free. They have 8 stores in the US (Santa Clara CA; Chicago IL; Baltimore MD; Woburn MA; Detroit MI; Mt. Laurel NJ; Long Island NY; Seattle WA) and 10 stores in Canada (Quebec City; Montreal (2); Ottawa; Mississuaga; Winnipeg; Calgary; Toronto; Edmonton; Vancouver BC). Each store has its own 800 number and FAX number, call the main number(s). International orders are to be mailed to the Canadian address, but they want payment in US funds! Lots of stuff, oriented more toward supplying last-minute requirements of companies than hobbyists, but perfectly happy to take your money in small doses (stores have no minimum order). The $25 minimum for certain items is no longer explicit, but they note that some items will "ship in factory minimum package quantities", which might be worse.

Maplin Electronics Ltd.,
P.O. Box 3,
Rayleigh,
Essex,
SS6 8LR
U.K.
Phone numbers: your international code +44 702 554161 for sales
+44 702 553935 Fax
+44 702 556001 Tech enquiries(2-4pmGMT)
"Over here [in the United Kingdom] the main hobbyist electronics supplier is Maplin Electronics who stock a wide variety of equipment. They have a catalogue which can be shipped for 10.65 pounds sterling by air or 5.50 pounds sterling by surface mail. They accept Mastercard, American Express and International Reply Coupons. They have at least one type of air-filled variable capacitor!" (Thanks to Kev White at Cambridge University).

Newark Electronics
Send catalog requests to:
Newark Electronics
ATTENTION CATALOG DEPARTMENT
4801 N. Ravenswood Ave.
Chicago IL 60640-4496
+1-312-784-5100
They don't have a single mail address or phone; instead, one is supposed to call the closest of three pages worth of branch offices. I don't feel like typing in the entire list (it's copyrighted, anyway :-), so send email for your "local" distributor, or call their administrative offices at the number above. They have a $25 minimum order; they are a Real Distributor, but accept small orders (over the minimum, of course). Their catalog currently 1248 pages; they are very complete (except, of course, for my favorite scarce item, the air-variable capacitor). Note that the catalog prices tend not to match reality all that often, so order by phone rather than by mail; prices tend to be higher than other places, but they have a lot of things that are hard to find from other outlets. Also note that they have six Canadian offices, and one UK office, and will take international orders at 500 N. Pulaski St., Chicago IL 60624-1019, +1-312-784-5100
(FAX +1-312-638-7652, TLX 6718690 NEWARK U).

Arrow Electronics, Inc. Catalog requests to:
Catalog Division Catalog Division
1860 Smithtown Ave. 25 Hub Drive
Ronkonkoma NY 11779 Melville NY 11747-9828
+1-800-93-ARROW
Minimum $25; they no longer have a catalog. They are a Real Distributor, but also didn't mind my placing a personal order (a couple of years ago).

MCM Electronics
650 Congress Park Drive
Centerville OH 45459-4072
+1-800-543-4330
+1-800-824-TECH (product questions)
+1-513-434-6959 (FAX)
Minimum $20 ($25 for charge cards, and they don't take personal checks), handling $1.95 + shipping. Oriented toward repair technicians, really heavy on VCR parts and somewhat overpriced doodads, lots of useful stuff not easily found elsewhere.

Fordham Radio Supply
260 Motor Parkway
Hauppauge NY 11788-5134
+1-800-695-4848
Tools for technicians. One or two items are not outrageously overpriced.

Jameco
1355 Shoreway Road
Belmost CA 94002
+1-800-831-4242
+1-800-237-6948 (FAX)
+1-415-592-8097
$30 minimum order (was $50), >$5 shipping & handling. Their most recent catalog may have reversed a long trend of abandoning parts in favor of PC compatibles, or it may not; one can always hope.

JDR Microdevices
2233 Samaritan Drive
San Jose CA 95124
Orders: +1-800-538-5000
+1-408-559-1200
FAX: +1-800-538-5005
+1-408-559-0250
Cust. Service: +1-800-538-5001
Tech Support: +1-800-538-5002
BBS: +1-408-559-0253

No minimum, $5+ shipping. Mostly computers now, but they haven't yet decided to abandon components; indeed, they recently dropped their minimum order requirement entirely.

Johnson Shop Products
P.O.Box 160113
Cupertino CA 95016

+1-408-257-8614
+1-408-253-6288 (FAX)
Catalog $1. No minimum. Shipping charge is based on UPS; very small orders that can be sensibly shipped in a first-class letter, include money for first-class postage. New and some used electronic parts.

DC Electronics
P. O. Box 3203
Scottsdale AZ 85271-3203
+1-800-423-0070 (orders)
+1-602-945-7736 (stock/price checks)
+1-602-994-1707 (FAX)
$15 minimum charge order, no minimum for checks, $3 min. shipping&handling. Wide array of ICs, good assortment of electronic components.

EasyTech Inc *** out of business? ***
2917 Bayview Drive
Fremont CA 94538-9932
11 May 93: "EasyTech no longer has an 800 number, and has dropped several lines. The last time I called them (2 months ago), I got the impression they were slowly going down the tubes..." - dts@banyan.com "Both of their 800 number and the customer services numbers are disconnected, and no new numbers are given." - lau@gandalf.rutgers.edu

International Components Corporation
1803 NW Lincoln Way
Toledo OR 97391-1014
+1-800-325-0101 (US & Canada)
+1-503-336-4400 (FAX)
Cabinets&Enclosures; Capacitors; Diodes; ICs; Potentiometers; Resistors; Sockets; Transistors; Books. No minimum order, $2 handling under $25.

Kelvin Electronics
7 Fairchild Ave.
Plainview NY 11803
+1-800-645-9212
+1-516-349-7620
+1-516-349-7830 (FAX)
Minimum order $20; S&H 5% of order ($5 minimum, extra for large stuff, overnight, export (like to Hawaii :-), and etchant; based on UPS charges). Lots of electronic parts & tools, some robotics supplies, model rockets.

H & R Company (Herbach and Rademan)
18 Canal Street, P.O.Box 122
Bristol PA 19007-0122
+1-800-848-8001 (Orders)
+1-215-788-5583
+1-215-788-9577 (FAX)
Minimum order $25 ($5 processing charge under $25), shipping $4.75 under $30; Most items are new overstocks, much regularly stocked stuff as well. Tools, electrical supplies, motors, mechanical components, robotic components.

SURPLUS ELECTRONICS:

All Electronics Corp.
P. O. Box 567
Van Nuys CA 91408-0567
+1-800-826-5432
+1-818-904-0524
+1-828-781-2653 (FAX)
$10 minimum, $4.00 S&H. New and surplus electronics.

Alltronics
2300 Zanker Road
San Jose CA 95131
+1-408-943-9773
+1-408-943-9776 FAX
Surplus electronics. $12 minimum, shipping per UPS.

American Science and Surplus (formerly JerryCo)
P.O. Box 48838
Niles IL 60714-0838 ### New address.
+1-708-475-8440
+1-708-864-1589 FAX
Surplus. *The* surplus place. Lots and lots of surplus. WWII gun cameras,
velcro, laser disk chassis, 6 volt VW wipers motors, LEDs, rubber brains,
you name it, they've had it. Catalogs are a really good time.
$12.50 minimum order (which includes the $4 shipping charge).

BCD Electro ### Out of the mail order business!
P. O. Box 450207
Garland TX 75045-0207
+1-214-343-1770
According to Barrie Britton (24 Feb 94), BCD has gone out of the mail order
business.

Fair Radio Sales
P. O. Box 1105
1016 E Eureka St.
Lima OH 45802
+1-419-227-6573
Surplus electronics. Heavy on parts for old Collins gear.

Hosfelt Electronics
2700 Sunset Blvd.
Steubenville OH 43952
+1-800-524-6464
+1-614-264-5414 (FAX)
No minimum, $3.75 S&H. Surplus electronics.

HSC Electronic Supply (Halted Specialties Co.)
3500 Ryder Street
Santa Clara, CA 95051
+1-800-4-HALTED Orders only
+1-408-732-1573 inside California and outside US

Surplus (new) electronics; new and used test equipment. Minimum order $10
($2 handling charge under $20), plus UPS shipping cost. Has three stores,
of which 3500 Ryder Street is one.

Marlin P. Jones & Assoc.
P.O. Box 12685
Lake Park FL 33403-0685
+1-407-848-8236
+1-407-844-8764 (FAX)
No minimum ($1 fee for under $10), shipping per UPS. Surplus electronics.

R&D Electronics
1224 Prospect Ave.
Cleveland OH 44115
orders: +1-800-642-1123 (tues - fri 9am-4pm sat. 9am-3pm EST)
info: +1-216-621-1121
fax: +1-216-621-8628
$10 minimum. Surplus electronics.
"Also known to stock many components, but this is not discussed in the catalog.
Local store, a cleveland institution, is called Electronic Surplus, Inc., and
has been there since '48. Third generation now runs it." -- wb8foz

Surplus Sales of Nebraska
1502 Jones Street
Omaha, Nebraska 68102
+1-402-346-4750
+1-402-346-2939 (FAX)
New and surplus radio electronics. Wide selection: air variables.
Catalog $3 (free with order, refundable with $25 catalog purchase).

Tucker Surplus Store
1717 Reserve St.
Garland TX 75042
+1-800-527-4642 extension 135
Surplus electronic gear; oscilloscopes and signal generators from the days
when dinosaurs with vacuum tubes roamed the earth (some solid state gear, but
all well used). Prices seem relatively high, and you'll be shocked to learn
how much it costs to ship a 75 pound oscilloscope by motor freight...
[Steve Brown, N8HFI:
In defense of Tucker, the have a broad selection, repair facilities, and
they certify the used equipment to meet the original specification and
warranty it for 90 days. Not every source does this:]

Davilyn Corp.
13406 Saticoy St.
North Hollywood, CA 91605-3475
+1-800-235-6222 (Ex. CA)
+1-818-787-3334 (CA)
+1-818-787-4732 (FAX)
Surplus electronic gear.
[has much better prices [than Tucker], but sells used equipment as-is. -N8HFI]

SPECIALTY COMPONENTS:

JAN Crystals
2341 Crystal Drive
P.O. Box 06017
Fort Myers FL 33906-6017
+1-800-JAN-XTAL (Monday through Thursday)
+1-813-936-3750 (FAX)
+1-813-936-2397 (plant)
They make crystals. Minimum order is $10, which might be one crystal, or might be two.

Crystek Corporation
2351/2371 Crystal Drive
P.O. Box 06135
Fort Myers FL 33906-6135
+1-800-237-3061 (M-F) (US and Canada but not Alaska and Hawaii)
+1-813-936-2109
+1-813-939-4226 (FAX)
They make crystals too. They were the cheapest last time I ordered, but I don't have an up-to-date price list. It took about 4 weeks, and they had said it would take 6.

ICM (International Crystal Manufacturing Co., Inc.)
701 W. Sheridan
PO Box 26330
Oklahoma City OK 73126-0330
+1-800-426-9825
More crystals. They were more expensive, but they have lots of pre-made crystals for various rigs, so they would probably be faster.

Amidon Associates
2216 East Gladwick Street
Dominiguez Hills, CA 90220
+1-213-763-5770
+1-213-763-2250 (FAX)
Toroid cores and related things. Very fast service. Now takes MC/Visa and phone orders.

Palomar Engineers
Box 455
Escondido CA 92033
+1-619-747-3343
Toroid cores and shielding beads.

RF PARTS
435 South Pacific Street
San Marcos CA 92069
+1-800-RF-PARTS (Orders only)
+1-619-744-0700 (main order line & delivery info)
+1-619-744-0750 (customer service, warranty, tech & applications, 10AM-4PM)
+1-619-744-1943 (FAX)
Tubes and transistors. $2 handling below $20 for US orders; $5.50 minimum

handling for Canada orders; they take foreign orders (but no handling info was given in the QST ad).

K2AW's Silicon Alley
175 Friends Lane
Westbury NY 11590
+1-516-334-7024
Free catalog, $10 minimum order. Semiconductors, in particular high-voltage diodes.

Small Parts, Inc. [New address and phone, 23 Dec 91]
13980 NW 58th Court
P.O. Box 4650
Miami Lakes, FL 33014-0650
+1-305-557-8222 Order department
+1-305-557-7955 Customer Service (ask for Mirta)
+1-305-558-1255 Catalog (ask for Elizabeth)
+1-305-557-8004 Custom-made Parts (ask for Ziggy)
+1-305-557-8005 Non-standard Sizes
of catalog parts (ask for Eric)
+1-800-423-9009 Toll free FAX line
$12 minimum. Mechanical parts, metal stock, Teflon(R) sheets, tools, wire-size drill bits (as in #61 size for PC board holes).

KITS:
(The terse "Note:" descriptions are from the ARRL Kit List courteously supplied by Ed Hare and Mike Gruber at the ARRL. For a much more complete list of kit suppliers, use the ARRL email server; send the following as the text of a mail message:

462. Re: Challenge: Cheapest (least expensive) homeb

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-25 17:31:57 UTC
From: dadams@cray.com
Message-ID: <1994Feb25.113157.19203@hemlock.cray.com>
Source record: 118501

I am not ready to get into this contest myself, but only because I
am trying to move the project to 220 instead of 2 meters. Now that
the FCC has opened the entire 220 band to the Novice class license
I think it is the perfect opportunity to get my sons interested in
working toward their first license.

Motorola makes a few chips with an entire low power dual conversion
FM receiver on a chip (the MC3363 or the MC13135 or the MC3362 etc.)
and another chip the MC2833 a low power FM Transmitter system. Each
of these require a few external parts, but only a minimal few. Order
data sheets MC2833/D, MC3363/D, MC13135/D, and Winter 1992 Communications
Quarterly reprint article. Also Application note AN980/D contains
instructions, board layout etc., for a 256 Channel Frequency Synthesized
Two Meter Amateur Band Receiver. The other documentes describe other
circuits/projects.

I got the boards and set of chips free.

I dunno, maybe I should try it first on 2 m just to make sure I can do it.

I'm working on a project which requires a signal to transmit about 100 ft. or so. All the sinal needs to be is a pulse or a steady tone in which it will send a high output into my circuit which will then activate a device of mine. If anyone could provide a scematic Digagram on how to build on of these, I would appreciate this very much...Also if someone cannot answer this, could refer me to a book which would cover projects of a similar nature....Thanx,

Back in the mid-1960's Novices could run phone (AM in those days)
on 145-147 MHz. The Heath Twoer was a cheap (for then) and simple
kit rig that was very popular. I and quite a few of my teenaged
friends got started on hamming this way. 2 meters may be too
crowded most places for that today, but it would sure be nice
if a cheap simple rig like this could recreate those times for
today's kids.

Perhaps my own bias, but in IC layout there is much discussion of L calculation
for traces. That's where I would look. Note that many PCB oriented books
treat L of traces as strictly parasitic.

Yer readin' the wrong books.
Try the ARRL UHF/Microwave Experimenters' Manual. Nice treatment of
MICROSTRIP elements. If you want more theory, back up a chapter to the end
of transmission media. They don't get into complex configurations like
spirals, but there is a long list of references for further reading.

476. Looking for a keyboard for a HaL Telereader

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-02-28 14:05:19 UTC
From: "Paul J. Anderson" <wrmed@mr.net>
Message-ID: <17772.wrmed@mr.net>
Source record: 118516
Cross-posted to: sci.electronics,rec.radio.amateur.homebrew

My dad has had a HaL Telereader for years (decodes CW, RTTY, etc). The keyboard encoder has partially failed (one row of keys doesn't work).

We traced the problem to the encoder and called HaL. They don't make it any more. I called the manufacturer of the chip (used to be General Instruments, now is MicroChip), any they said they don't make it anymore.

We did discover that a "standard parallel keyboard" will work. Looking at the schematic, it looks like uses 8 bits of data, a strobe, and an ACK line.

I could make a serial -> parallel converter and use an IBM style keyboard, but I would rather pick up another Telereader or parallel keyboard.

Hints?

Paul Anderson - N0RIK

: What would you recommend using for 3A at 4KV, I have seen some
: 2Amp 10000 volt "double diode" bridges in Nebraska surplus. These are
: setup for heat sink mounting. 2 in parallel ?

I would just use a series string of lower-voltage 3A diodes.

I hate to bring up the next point because, since it violates conventional
wisdom, it is bound to draw some flames. But what the heck...

You don't need to put resistors in parallel when you string
diodes in series.

There, I've said it.

Think about it. When you over-voltage a diode, it acts like a high-voltage
Zener and clamps at its breakdown voltage. So long as the current is
limited, no permanent damage occurs. Since all the diodes in the string
are in series, the current through each is the same. The current will be
limited to the leakage current of the lowest-leakage diode in the string,
typically a few microamps. Unless you exceed the SUM of the breakdown
voltages of all the diodes in the string, no catastrophic breakdown
will occur.

How about a long wire? A 100-foot wire would be about 15 wavelengths
which would give you tons of gain on the two meter band. I don't see
hwo you could get much cheaper than that. Of course, it would be a
bit hard to rotate :=)

Doug-

It should be possible to parallel diodes the way you parallel transistors: put a low-value "ballast" resistor in series with each.

For your high voltage requirement, be sure there is a capacitor (around 0.001 MicroFarad) in parallel with each set of parallel diodes, and be sure the capacitors have at least the same voltage rating as the diodes. This ensures that any voltage transient will be divided equally among the diodes in a string, rather than being determined by junction capacitance.

Note: Parallel resistors across each diode in a series string, serve no useful function. Slowly-varying voltage will divide according to the diode's leakage resistance, which effectively decreases as you approach its breakdown voltage. Further, you won't find many inexpensive, high-value resistors rated at 1000 volts dielectric strength! For example, an RC42, 2 watt carbon resistor is rated at 750 volts.

You can use a dish. But to get good gain, you need a very large
dish.
>
>If you have references, please share them.

Sure. ARRL handbook, RSGB handbook, ARRL antenna book. Plus
others available at your local library or ham store.

Give us the GI part number. I suspect many of us may have junk boxes
full of the encoders. Also note that a PC keyboard does not output
ASCII. It outputs a scan code that's interpreted by the PC bios to
an ASCII value. So you need a bit more than a serial to parallel
converter to make one work on your HAL.

I have built one and have a second partially complete. You would certainly
do better buying a TNC instead. DSRI has some with 9600 built in, and so
forth. The biggest advantage I see with the TAPR modem is the ability to
do bit regen, but that is only an issue for your full duplex packet
repeater, not for user equipment.

488. Re: How about VHF MOSFET's for 2-meter amp?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-02 00:36:41 UTC
From: Bob Lombardi <boblombardi@delphi.com>
Message-ID: <xE0LfkZ.boblombardi@delphi.com>
Source record: 118428

I built a 4 watt PA for a transverter based on one of the Motorola TMOS fets back in 86 or 87. I found the bias very easy to tweak for best IMD performance, and the matching quite easy; it is true that matching for lower power amps is generally easier than high power so that YMMV.

I did have to add a 24 V. PS to the station, but I pretty much already had one and only needed to expand the wiring harness. The thing gave me 4 W (+36 dBm) for around +23 dBm input power, which was pretty nice. And it was literally build, tweak once and on the air. No hair pulling, no swearing. (you would have had to been there while I tried to get some bipolars running to really appreciate that). I'd use another in a heartbeat.

This transverter was in Ham Radio, I think the VHF/UHF issue the year they got bought out.

I never had any trouble with static like the one guy said, and I do live in what is usually called the lightening capital of america, near Orlando, FL. Of course, I'm not doubting his word, and I did make it a point to put disconnect the antenna and put a 50 ohm load on the TR relay when not on the air. This was more to protect the GaAsFET front end than the output amp.

Just another $.02 worth....

>crowded most places for that today, but it would sure be nice
>if a cheap simple rig like this could recreate those times for
>today's kids.

Those old AM rigs were complex compared to what we can do with
modern ICs and FM. Using the Motorola MC2833 single chip transmitter
and the MC131135 single chip receiver, you can easily build a low
power crystal controlled HT. With a synthesizer chip added, a full
800 channel HT could be assembled, and with a power brick, a complete
mobile rig.

Motorola offers evaluation kits (free if you have the right letterhead)
including chips, circuit boards, and instructions for these chips. It's
really easy to make them work. A HT is a two evening project. Using these
chips, it's really simple to do a complete RF section for a 9600 baud
packet station. The MC131135 has a linearized output suitable for 9600
baud, and the MC2833 is direct FM. Highly recomended.

Yeah, *don't do that*. The carrier current rules require that you take affirmative steps to limit radiation outside the licensed complex. The usual way to do that is with "leaky coax" distribution. The power system is too uncharacterized for this purpose.

A*[cos(Wo*t) - delta phi/2 * sin(Wo + p)*t - delta phi/2 * sin(Wo - p)*t]

That really says it all. :-)

But perhaps a little simplified verbal description might be in order.
Modulation and mixing go hand in hand. You can't have one without the
other. Let's break down the FM equation into it's parts. The cos(Wo*t)
represents the carrier wave. The delta phi (don't have Greek symbols
on this keyboard) represents the deviation. And sin(Wo+p)*t and sin(Wo-p)*t
represent the upper and lower sidebands respectively with p being the
modulating frequency. So you can see that the upper sideband consists
of the sum of the carrier and modulating frequencies tines half the
deviation, and the lower sideband is the product of the deviation and
the difference between the carrier and modulating frequencies. So FM
has sidebands too, like AM, but multipled by the deviation. Note these
are *vector* quantities and don't combine in a naive way, and note that
all of these components wind up being multiplied by A, the signal amplitude,
a constant. Rule of thumb for FM occupied bandwidth: two times the highest
modulating frequency plus the deviation is occupied bandwidth. So a NBFM
transmitter with a highest modulating frequency of 5 kHz and a deviation
of 5 kHz will occupy approximately 15 kHz of bandwidth. The amplitude of
the whole complex wave is constant, but is shared among the components in
a fairly complex manner. For example there are certain modulating frequencies
that when combined with certain deviations will result in a carrier
with zero power, and all the power in the sidebands. These are called
Bessel nulls and are handy ways of measuring deviation.

>The other thing is SSB. I get the general idea of using power more efficiently
>by sending half the audio waveform as the other half is going to be a mirror
>image, and removing the carrier as we want to concentrate power on the signal
>instead of the carrier. What I don't get is how one removes the carrier and
>then adds it back again. Can someone explain that, please?

A*cos(wt) + a/2*cos((w+p)i*t+phi) + a/2*cos((w-p)*t-phi)

Again we're mixing, but this time the carrier has a constant amplitude, A, and the sidebands have a variable amplitude, a/2 where a is the amplitude of a particular modulating frequency. Notice the w+p and w-p parts that are the sum and difference frequencies of the carrier and the modulation, the upper and lower sidebands respectively. If we use a balanced mixer, the A*cos(wt) will cancel because of the 180 phase shift, removing the carrier. If we do this mixing twice, in separate mixers, but with one mixer having w shifted 90 degrees, and then combine the outputs, we can eliminate one of the sidebands. This is the phasing method of SSB generation. Or we can use a narrow filter to chop off the other sideband from the output of a single balanced mixer. That's the way it's typically done in amateur equipment.

What we have left is a faithful copy of the original modulation, but translated in frequency to a band near that of the original carrier. We can then use another simple mixer with a local carrier to mix this signal once again. We'll get a sum frequency that's a higher RF frequency, local carrier+modulation, and a difference frequency that's *constant* - modulation, or just the original audio with a DC offset. The constant is dependent on the *phase* difference between the local carrier and the original carrier. We pass the output of the mixer through a lowpass filter to get rid of the local carrier and sum frequencies, and we're left with a copy of the original audio with a DC offset. If we AC couple this to an AF amp, we have the original audio modulation.

Easy.

I need a source for some low voltage solid
state realys. I am making a CT interface to the
remote-control port on the TS850. The relays
must be able to turn on using the parallel port
data lines voltage to switch in various resistor
values to the remote control port.

Anyone have or know of a source? Radio shack
5v relays wont work. Dont want any external
power to the circuit. (want it to fit in
a DB25 shell).

Something similar to the circuit described
in this month's NCJ.

>will occur.
>
>

I understand what you're saying, but it still scares me. Without the
resistors the reverse voltage will divide very unevenly across the
diodes, depending on their individual leakage. Thus in a string of
diodes it seems likely that you'll have one or two reaching their
Zener "knee" every cycle. I realize that once that happens the other
diodes will take the remaining voltage because of the increased leakage
current of the zenering (did I just invent a word?) diode. The
question is: does that cause any long-term degradation of the diodes.
The only case I know that's even remotely similar is that of using the
emitter-base junction of a transistor as a zener, after which they say
it's not worth much as a transistor any more.

Not looking for flames, just understanding...

499. FM BROADCAST BAND RF AMP

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-03 00:47:16 UTC
From: dzarda@saucer.cc.umr.edu
Message-ID: <1994Mar3.004716.5198@umr.edu>
Source record: 118439

Does anyone have plans or know of a way to boost the output of the
BA1404 stereo chip? I have a small 88-108 MHz stereo transmitter and I
need to boost the signal to reach about 3 miles. I need something very soon!
If so please reply. Thanks.

Will a CMOS 4066 or its 4016, 4052, 4053, 4529, 4051, or 4551 cousins work? They are very low-power -- max. quiescent current is measured in microamps. Try powering them off a control line that you don't plan to use for signalling.

These things have an on-resistance of ~300 ohms, an off-resistance on the order of 10^9 ohms, and can not switch voltages outside of their supply rails. Supply voltage is anything from -0.5V to +18V.

Jason Saunders (maupb@csv.warwick.ac.uk) wrote:

: I've read the RSGB's RAE manual, and still have difficulty with their
: descriptions of FM and SSB. In FM, as I understand, the frequency of the
: carrier is modulated by the amplitude of the speech. So why does the bandwidth
: of the RF signal matter? If you have, say a 28Mhz carrier and the bandwidth of
: the Rf signal is 5kHz, why should that limit the audio bandwidth to 5Khz?

It doesn't. It's perfectly OK to use a modulation index of less than 1 (that
is, modulating frequency is greater than deviation), but it is normally not
done because of reduced signal-to-noise ratio.

Why? Let's say you modulate at a 20 kHz rate but with only 5 kHz deviation.
The sidebands are located at +/- 20 kHz from the carrier. That means that
your receiver bandwidth must be 40 kHz, even though the peak-to-peak
deviation is only 10 kHz. Wider bandwidth means more noise. If you had
used 20 kHz deviation, you would have had a 4 times louder signal with
about the same required receiver bandwidth.

: The other thing is SSB. I get the general idea of using power more efficiently
: by sending half the audio waveform as the other half is going to be a mirror
: image, and removing the carrier as we want to concentrate power on the signal
: instead of the carrier. What I don't get is how one removes the carrier and
: then adds it back again. Can someone explain that, please?

The normal way is to use a balanced modulator which outputs the sum and
difference frequencies (carrier +/- modulation = the two sidebands)
while suppressing the carrier. You could also generate conventional AM
(using an unbalanced modulator) and use a sharp-tuning crystal filter
to filter out the carrier and unwanted sideband.

At the receiver, you simply generate an unmodulated signal at the same
frequency as the (suppressed) carrier of the SSB signal and add the
two together before demodulation. (Actually, most receivers are superhets
which convert the received signal down to an intermediate frequency, so
the carrier is generated at that frequency.)

Yes, I have seen degradation of a transistor's beta when the base-emitter
junction is reverse-biased for a relatively long period of time.
Frankly, I'm not sure what causes that effect. But I have never heard
of degradation of diode characteristics from reverse-biasing as long as
the current is held to a low value. Don't forget, we're talking only a
few microamps here, since the current flow will be limited by the
lowest-leakage diode in the string.

I understand what you're saying, but it still scares me. Without the
resistors the reverse voltage will divide very unevenly across the
diodes, depending on their individual leakage. Thus in a string of
diodes it seems likely that you'll have one or two reaching their
Zener "knee" every cycle. I realize that once that happens the other
diodes will take the remaining voltage because of the increased leakage
current of the zenering (did I just invent a word?) diode. The
question is: does that cause any long-term degradation of the diodes.
The only case I know that's even remotely similar is that of using the
emitter-base junction of a transistor as a zener, after which they say
it's not worth much as a transistor any more.

Not looking for flames, just understanding...

Source record: 118447

For a string of diodes in series without a parallel resistor string,
the reverse voltage across individual diodes will depend on the leakage
current of each of the diodes as they approach breakdown.

This is not particularly nice, but I guess the current in diodes which
have broken down is limited to the leakage current of diodes which
have not broken down, so the diodes should survive.

However, the parallel string of capacitors, (which should be present
for transient protection), may not be so happy about the uneven voltage
distribution unless each capacitor has a voltage rating equal to the
peak voltage for the whole string.

I'd like to add a couple comments basically in support of this.

First, another thing that degrades with asking the BE junction to handle a reverse current is noise figure; this can be dramatic with relatively short pulses current. My point of reference on this is very low noise audio amplifiers; noise figures around 0.5dB, optimized for 50k ohm source impedances. A "trick" to include in your circuit designs for low noise amps is some way to insure that on power-on and power-off, no capacitors try to charge/discharge through the BE junctions of your input stages.

Second, how about a simple diode balance tester? Someone with an interest in this can go check some diodes and let us know quantitatively how much of a problem it really is. Tester: feed a transformer with a center-tapped high voltage secondary from a variac, so you can control the voltage. Ground the center-tap. On each end of the winding, put a capacitor, perhaps 0.1uF, rated at the peak voltage of the secondary (RMS*1.5 or so). Connect two diodes in series between the remaining ends of the caps. Measure the voltage with a scope at the junction between the diodes. If things are prefectly balanced, that voltage will always be zero. You should be able to tell from the shape, phase and amplitude of the waveform you observe there just what the imbalances are. You could use this jig to sort (match) diodes, if you really feel a need to.

Call'em up. I did after seeing the writeup in Quarterly Devices. Got
a MC2833 kit and a MC13135 kit.

>I'm not sure how simple these circuits are to understand. The receiver
>schematic includes approx 35 components. Both examples given are tuned
>to 49.7 MHz, so adjustments would need to be made for HAM use.

Seemed simple enough to me. There are 27 parts counting all the resistors
and bypass caps, but there are only 5 critical components aside from the
chip itself, and only one of those needs to be changed to scale the
frequency, the first LO crystal. The chip is rated to 200 MHz, but I've
pushed it as high as 223 MHz with little or no loss of performance.
Note that it takes about 0.75 microvolt for 12 db SINAD, so you might
want to add a RF stage and bandpass filter ahead of the kit for good
performance. A tuned input would be a good idea in any case to limit
image and intermod problems. In a transceiver this could be a common
input/output network.

: I'm looking for a Lexical Analyzer for DOS.
: How about a 'port of "lex"? Does anyone know where one may be found?

In my travels, I've run across at least 3 versions of Lex implemented
in C. (And another that does Turbo Pascal.)

First, there's AT&T Lex. You can't get the source to this.
(A version of AT&T Yacc was out, but AT&T sicced their lawyers on
people. No bit deal, Bison and Byacc are as good or better.)

Next, there's a Lex written at University of Waterloo (by
Charles Forsythe?) that was released on a DECUS souce code tape.
It has an incompatible source languge format. This was available as
a port to DeSmet C (a now obselete "classic" ie. Version 7 level compiler)
from the C Users Group, sold (for a while) by the Austin Code Works,
and is (I think) the lex in the MSDOS/C directory in the Simtel echos
sites C.

Finally, there's Flex. This is a souped up Lex written at UCB that
is the most common. It gains its performance improvement at the
expense of radically incompatible file input compared to AT&T Lex, but
as it's now the defacto standard, this is the route to take.
Available in the TXTUTL, GNUISH and DJGPP directories under MSDOS
on a Simtel echo. Also just about every where else (Linux release,
C Users Group, Austin Code Works, and wherever comp.sources.misc is
archived).

Well, I was doubting you on the resistors, but looked at my old
RCA transistor/diode manual and couldn't think of a good
response. But I'm primed for the capacitors!

The RCA manuals points out that the capacitance of a diode is
small. In a series string of diodes the later diodes are in
parallel with the normal capacitance-to-ground all wiring has.
Since this is larger than the capacitance of the first diode in
the string, then on a transient the first diode will see the
majority of the total voltage. The capacitors across the diodes
swamp out the capacitance to ground resulting in even division of
the voltage.

PS: Maybe the resistors are there to protect the capacitors,
perhaps even when a diode opens?

>At least, I know that "MKS Toolkit" has a lex product. I also think that GNU >BISON (their LEX clone) is available for DOS.

bison is not a lex clone---it's a yacc clone. The GNU clone of lex is called flex.

And as far as I know, flex will compile under dos (I use it on the UNIX side, but I seem to recall a Makefile for dos). I don't know if bison will compile under dos, but I believe byacc (Berkeley yacc) will (again, I seem to recall a Makefile for dos being in there). Don't quote me on either of these, though.... :-) (Of course, since they're free, you have little to lose.)

Oh, one other point to make. If you use bison as a yacc substitute, keep in mind that all code you produce has to meet the terms of the GPL. This does *NOT* apply to flex. Any followups on this point (i.e., GPL is good/evil) should, of course, be directed to another group (actually, I'm curious as to how this topic ended up here in the first place).

>If you find one, remember to check out which C compiler it works with.

Since when has lex or yacc output been specific to one compiler? Granted, there may be some issues between ANSI/K&R C, but other than that, lex and yacc should produce rather portable code (unless you have a badly-written lex or yacc ... and if that's the case, I wouldn't trust it anyways!).

"Radio Engineer's Handbook" by Fredrick E. Terman, 1943
has formulas and correction tables for flat spiral
inductors in circular, rectangular, and square shapes.
Since the pcb traces are differently shaped than round
wire or flat wound strip, the formulas will be starting
points. These coils are in free space away from ground
planes, so single sided pcb construction is equivalent.
I think Terman also analyzes self resonance due to dis-
tributed capacitance in inductors generally.

I've done this some time ago, yes you need to change the crystal. I got some crystals at hamfests and such for cheap. If you wanted a specific frequency, you may have to order it. May be too expensive, though.

Don

Here are a couple of companies

Melcor
Materials Electronics Products Corporation
1040 Spruce Street
Trenton, New Jersey 08648
Ph. 609 303 4178
FAX 609 393 9461

Marlow Industries, Inc.
10451 Vista Park Road
Dallas, Texas 75238 1645
Ph 214 340 4900
FAX 214 341 5212

Have ordered from Marlow. Their standard single stage tecs run from $12 to $55.50. Special single stage tecs run $23 to $150. Multi stage tecs run $43 to $810. (tecs = thermoelectric coolers)

Both companies will send you a very nice application booklet if you give them a call. The book gives enough info to design simple cooling circuits. Hope this all helps , I've got my eye on a used set for a special coffee cup coaster that would heat with the handel in one direction and for tea cool with the handel in the other direction. Right.

: However, the parallel string of capacitors, (which should be present
: for transient protection), may not be so happy about the uneven voltage
: distribution unless each capacitor has a voltage rating equal to the
: peak voltage for the whole string.

Funny you should mention that. I don't think the capacitors are needed either.

I can think of two reasons for the capacitors. One is as you said: for transient protection. However this could be done with a single capacitor (or two for center-tapped secondaries) across the secondary. For that matter, seems to me that a transient suppressor on the primary should take care of the matter.

The only other reason I have heard for putting cap's across the diodes is in case different diodes in the string turn off at different times due to different carrier lifetimes. But if you use all diodes from the same manufacturer's batch they will be very well matched.

But even if they aren't, remember that the voltage across the diode string is close to zero at the moment of turnoff. For a normal capacitor-input power supply, the turnoff point is near the top of the 60-Hz sinewave where the voltage is changing very slowly. It will take a good portion of the 1/60 second cycle time (several milliseconds) before the diodes are reversed-biased significantly.

But let's take a worst-case condition: A diode rectifier feeding a resistive load or a choke-input filter. With a 60-Hz line, the reverse voltage across a string of, say, 5 diodes won't reach 1/5 of peak for 1 / (5 * 60 * 2 * PI) sec = .53 milliseconds after turn-off. So the slowest diode would have to turn off >= .53 ms after the next-slowest diode to even potentially cause a problem. That would take some awfully slow (and mismatched) diodes!

I would like to get some feedback on a vertical antenna for the reception of the 108-138 MHz aircraft band. I currently use a discone antenna, that seem to work much better than a tuned dipole. I thought the discone antenna had unity gain?? I want an antenna with high gain, omni-directional, vertical polarity. I have seen 144 MHz antennas with a gain of 9 dB, but what will the gain be at 125 MHz?? How can I make one or where can I get one? Please help.

Must be something wrong with your dipole. I assume it is set
up as a vertical?

> I have seen 144 MHz antennas with a gain of 9 dB, but what will
>the gain be at 125 MHz?? How can I make one or where can I get one?

A 144 MHz antenna will probably have little gain at 125 MHz.
But these "High Gain Omni-Directional Verticals" are neither. They
exhibit gain because they are not omni-directional.

These antennas exhibit a squished pattern that looks to the
horizon. They have a nice big null overhead. This is not what you want
to listen to aircraft, unless you intend to listen to aircraft on the
ground that are all around you. If you wish to listen to aircraft on
the ground at an airport, then a Yagi is what you need.

For overhead omni-directional listening on the aircraft bands,
I suggest a groundplane.

If you want to know what the best antenna is, go to an
airport. Look at their antennas. Bear in mind that the Air Traffic
Controllers have the following criteria: Bigger budget than you, 100%
reliability, best performance. Those criteria are usually met with
groundplane and hairpin groundplane antennas.

If you really want to do it right, ask at their radio shop -
which will be on the airport property or nearby - what make and model
they use.

The Garmin GPS-10 receiver board is less than $350 in quantities of 2 (two). It is an 8-channel
receiver with NMEA output. They can supply a program that runs on a PC and displays the data
from the GPS-10, connected to one of the serial ports. The above price includes the antenna.
One of the reasons that we like it is that is only consumes 1 watt (0.2A @ 5V). Garmin can be
reached at (800)800-1020. Note that this is not an endorsement, etc., etc.....

526. Tuner-tuner

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-05 01:00:03 UTC
From: rfm@urth.eng.sun.com
Message-ID: <RFM.94Mar4170003@urth.eng.sun.com>
Source record: 118466

In the March QST, kinda near the back, there's an ad from Palomar for a gadget called the "tuner-tuner." (For all I know this ad has been in every QST since 1927, but this is the first time *I* noticed it.)

What the ad says this gadget does is allow one to adjust one's antenna tuner precisely without having to transmit. Operation is described as:

1. Put the gadget between the transceiver and the tuner (I assume they mean electrically, not physically)
2. Flip the knob on the gadget from OFF to TUNE. A strong noise will be heard in the transceiver's speaker.
3. Twiddle knobs on the antenna tuner until the noise goes away.
4. Flip the knob on the gadget from TUNE to OFF.
5. Transmit away, at 1:1 SWR.

It's not stated, but I assume that the tuner will be adjusted for the frequency the receiver was tuned to.

Now, my questions:

1. just how does this gadget work?

It seems to me that what it's doing is sending low-power broadband noise out through the tuner, line, and antenna, and passing the reflected noise back to the receiver. When the the tuner is adjusted right, the impedance matches and there is no reflections, hence no noise for the receiver to hear. But how does the receiver not hear the original noise source (when answering, be aware I've not yet figured out how a SWR meter manages to measure direct and reflected power separately either.)

2. how can I build one? [this is why this is in r.r.a.homebrew and not .misc]

Looking at the picture, there's a knob and a case. Palomar's asking $100 for this beast, so given labor, Palomar's markup, and the cost of knobs and cases these days, I figure total parts cost has to be about $10 max.

I have a sneaking suspicion that this is a well known hack that's been around since CW first replaced spark, but I haven't found anything in the books I've looked at (ARRL Handbook and Antenna Book.)

Commercially available high voltage rectifier modules consist
of a lot of conventionla silicon rectifer dice stacked in
cascade _without_ any equalizing components in parallel with
the individual rectifiers. Manufacturers can do this because the
dice all come from the same wafer and are therefore very well
matched, both in terms of capacitance and in terms of leakage.

There is a real problem in series stacks of _unmatched_ rectifiers.
When a recifier is avalanched a lot of charge carriers are created
and injected into the junction. It takes time for these carriers
to be swept out by the field. This can cause significant amounts

of current to flow in the rectifer at the wrong time, and that leads to unexpected heating of the device. Whether this is a problem depends on the luck of the draw for most of us.

>lowest-leakage diode in the string.

Am I seeing a "mixed metaphor" here? Leakage current flows in
a reverse biased rectifier at voltages _below_the_avalance_voltage_.
When a good junction avalanches, its dynamic resistance becomes
very low and the current will rise to as much as the source can
provide. There is some similarity to a spark gap switch - the
resistance is very high until it is triggered, and then the
resistance becomes very low.

Avalanching a junction does degrade it. The first thing noticed
is usually that the leakage increases. If it's a low noise
transistor the noise figure degrades. If it's a bipolar transistor
the beta degrades.

Source record: 118319

Hello.

I would like to know if any of you here on r.r.a.h have assembled
and used the Ramsey SA-7 preamp.
I am planning to get a few of them and use them for TV and FM DX.
I will have one for FM, one for UHF, and one for VHF.
I have three seperate antennas for those bands, and seperate feed
lines too.

Will it be difficult to design a filter system where only the de
esired band(ie FM, or UHF TV) get amped by the SA-7?

I plan on buying three of them, and I would like to know what I
am getting into before I plunk down the $$$.

By the way, here are some specs:

freq range:100kHz to 1000mHz
gain:>20dB
noise figure: < 4dB
NEC microwave transistors are used in the design.
They are $14.95 each in kit form from Ramsey.
Ramsey is at: (716)924-4560

Thanks.

You can build one for about $10 or so. It is just a variation
on a noise bridge. My 1990 ARRL Handbook has a schematic. RadioKit also
sells a noise bridge. Or you could get the MFJ noise bridge for
about $50. Set the controls on the noise bridge to 0 reactance
and 50 ohms resistance before you tune. I built one from the
Ham Radio Magazine articles a few years ago. It really works.

Whoa, now! The Friendly Candy Company has something to say about this.
There are strict power limits for such unlicensed devices broadcasting in
commercial broadcast bands. Maybe somebody else has specifics, but I'm
almost certain it's real flea power and a definite limit on antenna and
feedline length.

You NEED it very soon? Hmmmm.

You probably won't see any improvement in the pileups. I am assuming that lots of stations want to work Singapore (9V1 for DX types). Problem is, most are probably calling on the same frequency (within 100 Hz), so a tighter filter won't help.

What will help is to have an RIT control and continually vary your frequency receive frequency over a narrow frequency range, perhaps a kHz or two.

However, 12 MHz ECS clock crystals sold by Digi-Key do make nice Cohn filters. Use 3 crystals and 470 pF capacitors. The input inpedance and output impedance just happen to be close to 50 ohms. (Some people just get lucky). Cascading two of them, I got a 3 dB BW of 379 Hz and a 6 dB BW of 427 Hz.

Finally, since you asked, adding more filters will improve the skirt selectivity, making stations out of the passband weaker. 4 crystals is probably OK for a CW rig, though I use 6 in one rig and 7 in another. Increasing the capacitor values will decrease the bandwidth, but will also decrease the impedance. Impedance matching is important to maintain the proper filter shape.

I am trying to work out a DSP filter applied to ham radio data communications (Amtor, RTTY, Pactor and Packect modes).
I am considering the following performances :

- AMTOR/NAVTEX:FIR Band-pass filter with 60dB att. at 60Hz out of the corner freq, center freq at 2210Hz, bandwith of 300Hz (corner freq. at 2260Hz-2360Hz)

- HF Packet: Two different band-pass filter could be selected:
*[2310-2110 mark-space]: BP , 60dB att, center freq. at 2210Hz, bandwith of 900Hz, (corner freq. at 1760-2660Hz).
*[1445-1275 mark-space]: BP, 60dB att., center freq. at 1360Hz, bandwith of 900Hz (corner freq. at 1810-1725Hz)

- RTTY: Multiple FIR band-pass filters, 60dB att., bandwiths of 135,150,180,225,300, 600 and 900Hz. Central freq. at 1360, 1700, 2340, 2210 and 2550.

- PACTOR: BP with 60dB att., center freq. at 2210, bandwith of 600Hz (corner freq. at 1910-2510Hz.

- BPSK Packet (A0-13): BP, 60dB, central freq. 1600Hz, bandwiths of 150, 200, 300, 600, 1200 and 2400Hz.
The idea is to cover most of the formats supported by different TNC manufacturers.
To calculate the effective bandwith of the filter I used Bfsk= 3*Bauds, Bpsk=2*Bauds (required bandwith of the channel).

Questions:
- Do you guys agree with these settings?
- How calculate the group time delay for the used FIR filters (around 400 taps with a Kaiser window)
- What would be the maximum delay allowed for AMTOR (i.e) operation?.
- Any suggestion?.

Jason,
When you generate a SSB, and AM for that matter, signal the audio
information that modulates the carrier also mixes with that carrier to give
you
"bandwidth." To generate a 20khz tone on a 28MHz SSB signal, you need to
have
20khz of bandwidth. FM is very similar, instead of generating amplitude you
generate
changes in the frequency. Thus the name Frequency Modulation, as I'm sure
you know. FM however, has a multitude of sidebands instead of two. FM gets
much more complicated in terms of bandwidth vs modulating frequency. Might
I

suggest the ARRL handbook for more details.

Going from 600 Hz to 400 Hz may not be enough of a change to make
a significant difference. You might want to shoot for a bit narrower.

I'm assuming the circuit has the capacitors in series between input
and output with shunt capacitors at input/output and the junctions
of each pair of crystals. Increasing the capacitance should narrow
the bandwidth. It will also lower the resonant frequency a bit
and increase the insertion loss slightly.

Zack Lau (KH6CP) (zlau@arrl.org) wrote:

: ... Increasing the capacitor values will
: decrease the bandwidth, but will also decrease the impedance.
: Impedance matching is important to maintain the proper filter
: shape. ...

To clarify, the load impedance is not really matched to the crystals,
it is matched to the source. Consider a single-section series crystal
with no matching capacitors. So long as the crystal series resistance
is small compared to the load resistance, the crystal has no effect
on source/load match at resonance.

When you add the shunt capacitors on input/output, you basically have
added L-networks at both ends, with the crystal providing the required
series inductance to effect the proper match. (The crystal looks
inductive above resonance.) The "L-network" transforms the 50 ohm
source/load impedance down to a lower value, which increases the
loaded Q of the crystal, narrowing the bandwidth. That also increases
the insertion loss, which is proportional to (loaded Q) / (unloaded Q).
The bigger the capacitor, the greater the impedance transformation and
the narrower the bandwidth.

In the following "schematic", L is the net inductance of the off-resonant
crystal, and R is the crystal's effective series resistance:

```
L-network L-network
|<---------->| |<---------->|
```

I thought about one of those, but I thought there must be a 0 $ answer.
So on my rig I try to get the same results by: (FWIW)

1: RF gain at minimum
2: AF gain at maximum
3: advance RF gain until some noise is heard.
4: adjust the antenna tuner for maximum noise. This should be a good starting place.
5: start checking swr at low power (to be considerate of others and your finals).

Good luck

Has anyone ever tried to use a switching type power supply to handle the 12 volt, approx. 20 amp requirement of typical 100 watt SSB HF rigs?

I realize that this is not customary, and is probably not recommended, that's why I'm asking.

Any problems with whine, poor transient regulation, etc?

I used one of these to power a Metron MA-1000 amplifier (12V, big amps during TX)... I got alot of loud popping noise (accoustic) from the supply during SSB current swings (along with unstable output voltage). Not sure if it was RF getting back into the supply or the dynamic load current, but anyway I did not continue using the supply for this application. 73 Dave WB0GAZ.

549. Reducing Tube Filament Voltage

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-08 13:50:14 UTC
From: drs@ccd.harris.com
Message-ID: <1994Mar8.135014.15825@ccd.harris.com>
Source record: 118339

In my reading about linear amplifier design and construction I have noticed in a couple of writings that if the filament voltage on say, a 3-500Z tube, is reduced from the typical 5.0 VAC to around 4.8 or 4.9 volts, tube life can beextended several fold.

In an article by AG6K on QSK for the TL-922 and SB-220 he mentions that a good method of reducing the filament voltage (at the socket) is by using smaller guage wire from the transformer to the socket. He mentions that it should have good (teflon) insulation. My question is: Is this really the best way to reduce the voltage? Seems like varying line voltage would necessatate using some sort of rheostat? Any ingenious methods out there? I am planning onusing a step-start relay to initially start the filament voltage low to reduce inrush current on a 4-1000 tube.

I have already implemented his method of biasing the tubes by putting a string of diodes in the cathode return line. This is in place of using a high wattage zener. This works fine, as you can fine tune the idle current on the tubes by the number of series diodes.

I once used a 3 lb switching power supply made for Yaesu 757. It worked
fine with good antennas. I purchased it because I wanted a light rig;
a mobile rig with a regular PS is heavier than a rig with a built-in PS.
With room or attic antennas this PS generated extensive noise despite
multi-stage filtering. Imagine my consternation when I tried to show my
rig in an elementary school using a few feet of wire and all the children
could hear was noise! Also the PS was once damaged by a static. I replaced
this PS by a one with transformer, and now ithe new PS's buzzing noise and
a large weight irritate me too.

|> 5: start checking swr at low power (to be considerate of others and your finals).

I have been disappointed when trying to tune the tuner by listening. It seems
to be due to:

1: The input impedance of the receiver is often much different than 50+0j ohms.
2: You can barely detect a 3 db signal change (even with the AGC off), and
a 3 DB loss probably corresponds to something like 3:1 SWR (I don't
have my handy little Forward/Reflected SWR nomograph handy...)

Sometimes if I am tuned correctly for transmission, I can get a noticeably
better receive signal by re-adjusting the tuner...

What a beast of a power supply... Mine is only a 42 amp Lambda model.
I don't have any extra filtering, except one toroid on the rig's power cable,
and I have no problem with RFI. BUT, if your antenna is right next to the PS,
you will hear some noise.

I do have a wierd problem though: The PS sort of acts like a speaker.
on SSB, it buzzes in step with the voice peaks, and on AM, I bet you
could almost make out what I am saying. Also, it buzzes when the toaster
in the kitchen is on. This is handy for letting me know then the toast is
ready...

You see millions of the 5 volt models at swap meets and surplus places.
A lot of people use 3 of them in series, each one turned down half a volt
or so.

Source record: 118344

Well, I have obtained a copy of FLEX and made it compile (When the person who wrote the MAKEFILE said that it *should* compile obviously hadn't tried... under MeSsyDOS, that is...) It seems to produce the "sample" file OK, but there appears to be something wrong...

First, you see the line:

#define yyleng (yy_cp - yy_bp)

Then, as if to be clever, you see lines in the code that do things like:

yyleng = 1;

AND (it gets better...)

yyleng++;

Yeah, right!

Either this version of FLEX is 'broke, or the lexical construct is flawed, or was written for a different version...

I grabbed CUG290 from a local BBS, and it included a DOS compilation, but it somehow failed to include a file called "skelcom.h" An archie search has failed to locate that...

BTW, I'm trying to compile the "z8dev" package. This was found on keos.helsinki.fi. It requires both LEX and YACC... The YACC was no problem (I used BYACC...)

Thanks,

<Clint>

555. CATV freq. shifting device needed

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-08 23:52:16 UTC

Greetings,

I have a strange request. It is not directly related to amateur radio, but the folks here (and on catv) will probably have the most experience in doing things of this nature. :)

Her in San Jose, CA, we have an old CATV plant that uses two cables due to poor bandwidth on each (i.e. 35 channels on each cable). Therefore, in order to change channels, you usually have to get up and hit an A/B switch to switch which cable is going into the TV (i.e. to go from a Fox channel to CNN, you have to go from 12A to 12B). This makes a cable-ready TV pretty useless. What I want to do is take the 'B' channels and do an IF add to move them up the CATV freq spectrum and combine the two cables into one. So instead of having 1-35A and 1-35B, we have 1-35 and 40-75, for example. I know the CATV spectrum is not contiguous. Has anybody done this, or have a good idea on how to do it. Please respond directly and I will post a follow-up if there is interest. Pointers to plans would be great!

Thank's in advance,
-=Chris

>is absolutely necessary or can I just use any type with the proper capacitance
>rating? If I need the special type of capacitor, what is the difference?

Different circuit elements have different requirements. That's why there
are different capacitor types with the same voltage and capacitance ratings.
You have to understand the purpose of a particular capacitor in a given
circuit to determine what type of capacitor is suitable. Silver mica
capacitors are generally used where accuarcy and known temperature
characteristics are required. Disc ceramic capacitors are more likely to
be used in non-critical bypass or coupling circuits. Chip capacitors are
used where low inductance packaging is critical, or where space is very
tight. Tantalum capacitors are used where high values of capacitance in
a small space are needed, such as for power supply filtering or audio
coupling. Metal clad polyester capacitors are used in applications similar
to those for silver mica where stability of value, and often RF current
carrying capacity, are critical parameters. Unless you understand the
reason why a particular capacitor type was chosen for a given design,
use the type specified.

Yes, but at some cost in tube Gm. Note that reducing the filament voltage is a *must* at VHF+ because back bombardment would otherwise overheat the cathode and lead to *very* short tube life.

> In an article by AG6K on QSK for the TL-922 and SB-220 he mentions that

>best way to reduce the voltage? Seems like varying line voltage would necessatate using some sort of rheostat? Any ingenious methods out there? I am planning onusing a step-start relay to initially start the filament voltage low to reduce
>inrush current on a 4-1000 tube.

That isn't the best method, it's just a cheap way of adding fixed series resistance in the filament circuit. A rheostat is better, and a variac on the primary of the filament transformer is better yet. You want some adjustment capability because you'll want to raise filament voltage as the tube ages and emission drops off. And a variac will allow you to bring up the filaments slowly at power on, which will also increase tube life.

>is absolutely necessary or can I just use any type with the proper capacitance
>rating? If I need the special type of capacitor, what is the difference?

Use the right type. There are so many different kinds for different uses...
Tantalum are "solid state" replacements for electrolytics. Large values, low voltage, for decoupling or filtering.
Ceramic disk are cheap, small value, high voltage, for decoupling, filtering, DC blocking, etc. Type NP0 are temperature stable for use in oscillators and such.
Chip caps are leadless, surface-mount types. Very low inductance due to no leads, for UHF/microwave applications.
"Metal clad" sounds like the ceramic compression trimmers used at RF freqs. High quality, low-mid value variables for trimming tuned circuits.
Silver mica are stable mid-high voltage, often used in LC filters.

Get a catalog from Digi-Key or Mouser for a good selection of caps.

Regarding my posting about Motorola GPS receiver boards:

It seems to have generated a lot of email.

Please get information directly from Motorola's Position
and Navigation Systems Business division if you
are interested. Call (708)-480-8000 and then follow the
directions about calling (800)-4-ONCORE. No, I don't
know what they cost in unit quantities. No, I haven't
hooked one up to my ham station. No, I am not interested
in coordinating a group purchase. I'm just giving you a
pointer to further information. Thank you.

Rick Karlquist N6RK

I'm working on designing an 8-pole Chebychev crystal filter,
using the equations and techniques in the May 1982 QST article, "A
Unified Approach to the Design of Crystal Ladder Filters."
Unfortunately, the table of normalized k and q values for a 0.1db
ripple filter provided in the article only goes up to order 5.

It seems to imply these (and the pre-distorted tables) are
from the Handbook of Filter Synthesis by Zverev, which I cannot find
locally (the library here is *horrible*). If anybody is familiar with
this article and/or this Handbook and would be so kind as to send me a
copy of the tables, I'd appreciate it very much.

I don't know about ingenious but you could try putting in series
two back-to-back germanium rectifiers (or two suitable germanium
transistors diode connected, i.e. base shorted to collector). That
should give you about a 0.2 volt drop.

I've accquired an Alliance rotor motor with no control box. The rotor
takes 5 wires, has the rotating mast thru the body and the mast top clamp
on the side of the case. I've been told this style is often used as an
altitude rotor on Satellite setups.
Questions:
1. What voltage does it take to turn the motor? AC or DC?
2. WHat are the pinouts for the five wires?
3. What is the model number or other ID's? (nothing on the case but Alliance).

I can open it up to get the pinouts, but I don't want to burn it out with
the wrong voltage etc.
I'm planning to use it to turn small VHF/UHF antennas.
Any positive responses are greatly appreciated!!!!!

<get a stable signal once I deviated very much from the frequency it was
>designed for. Is this due to the crystal?

No, it's due to the fact that you're no longer using the crystal for frequency
control; once you try to pull it too far, the LC components around it become
the dominant control element. What you need to do is get a crystal for 6m
and change the crystal so you don't have to try and pull the frequency so far.

Can someone tell me where or how I can find inexpensive software which will allow me to use my old Macintosh 128k (upgraded years ago to 512k) as a simple, functional oscilloscope. I would like to do some simple experiments with my children, probing electrical circuits or exploring speech signals. Surely there is some way to easily use the microphone jack as a source of input. I need to sample the signal being probed, write to a file, then use that file to create a graphical display of the signal. Maybe one can do it in real time also. Any help would be appreciated, I have this old mac with which I can do nothing useful and this would be a worthwhile project. If the mac can not be used this way what about my much newer PC?

Hello Catherine..Im Bob Nagy at UT Botany department..Here is how to
check low level mag fields. I manufactured an inepensive mag field
meter a few years ago..but could not sell them well...Ill tell you
how to make one. You take Radio shack's 30 dollar'ish analog audio DB meter
and remove the condenser mike element. You then take some 28 gauge wire,
50 feet of it..and make a small coil about 1.5 inches in diameter.
Take the two ends of that coil..strip and tim them..and solder them
to the two connections where the mic element was. Nothing else to do.
You can put the coil-sensor in a small plastic box and screw it to
the underside of the audio meter..That was my product..It seems that
calibration was un-nessasary and that a reading of -2 on the 60db
scale equated to the lower level that had been linked to damage in
the Denver studies. (anything above that) We have run many tests on
plant tissue here at a number of frequencies and show nothing
concrete. The word today is "prudent Avoidance" I still have a few of those
meters, and Id be glad to loan you one.

Toodles-
Bob

There one more good reason to put a capacitor parallel with a power rectifier diode. Carrier lifetime in typical diode happens to cause fair amount of RF noise in the 1 - 15 MHz band. The noise is very sharp mains frequency pulses. About 1 nF ceramic capacitor parallel with each diode with very short leads takes most of this noise out. The curious thing is, that capacitors before and after bridge rectifier are not effective.

Very few books (maybe Rohde's) deal with this phenonema, but I have read about it and made several experiments with various silicon rectifiers. Good old selenium rectifiers are free from this kind of noise.

Newsgroups: rec.radio.amateur.homebrew
In-Reply-To: <2klf26$olr@dawn.mmm.com>
Organization: University of New England, Armidale, Australia

Ron,

There are WEFAX converters available from UKW Berichte in Germany.
These are very good ones, but pretty expensive. My friend in Finland
has one and is satified with it. I have address and some more data
at home.

Also plans and PCB patterns for some WEFAX converters were published
in the Wireless World about 15 years ago. These are still usefull,
you only add a modern pre-amplifier.

Timestep Limited in U.K. also sells 1.7 GHz WEFAX converters.

The output of WEFAX systems is around 137 MHz, you must change some
crystals and retune output circuits.

A small slice of history ... Old (pre-1980's) silicon power diodes were
not controlled avalanche type. They were destroyed by overvoltages. All
new rectifier diodes (except some Schottky diodes) act like zeners and
are destroyed only (in practice) by overheating. Thus capacitors are no
longer needed if the wiring is equal for each of the series connected diodes.
Some power rectifier manuals explaint this.

The RFI (or should I say EMC) problem still persists, capacitor is needed
even for one diode to suppress HF noise caused by the diode switching action.

boley.d%wec@dialcom.tymnet.com wrote:
: Anybody have any comments on the DownEast microwave kits ??

The no-tune boards are really a compromise to let people
get on the microwave bands without expensive test equipment.

They are fine for routine work such as packet links
and casual operating. But, if you want the ultimate
station, no matter what the cost, you can do better.

For instance, the current drain is much higher than if you
were to use say, tuned GaAs FET multipliers. But for
portable use, you have to be careful what you use to tune
your circuits with. Cheap trimmers tend to be unreliable.
Below 1 GHz, I like to use high quality piston trimmer
capacitors.

Also, microstrip filters tend to be more lossy than filters
made by milling out blocks of brass. Thus, you need
more gain ahead of the mixer/filter to get the same
noise figure, which degrades dynamic range. Usually not
important, though Gary has pointed out the possibility
of a nearby Ku Band uplink hammmering your receiver.
Eliminating the MMICs on the RF input of a receiver
and using just GaAs FET stages usually results in a
better noise figure and dynamic range.

The mixers are actually pretty good, though there are
better ones. The DBM in my S band converter has
only 5 dB of loss (bought it at a Microwave Update auction).

If you are going to be driving a kW amp and need the cleanest
signal possible, I'd recommend you chop up a no-tune
transverter board and put the LO, receiver, and
transmitter into separate shielded enclosures, hooking
up the RF connections with SMA connectors.

Look at what the cops are driving. Ford Crown Victorias seem popular
with them, as do Chevy Caprices. Order your's with the same fleet codes
that they use and you'll have a car that works well with radios. (It'll
also have the heavy duty electrical system, cooling system, and suspension
of a cop car.) Get the same color scheme that they use for their unmarked
cars too, that way the antennas won't draw suspicion. (And you may avoid
some tickets.)

It gives you a very crude indication of magnitude in that you can compare the deflection with that of the earth's magnetic field, or with a reference magnet. Not terribly accurate, I agree, but fine for some work.

And no emissions controls. :-(Diesel smoke is a suspension of carbon particles impregnated with the byproducts of combustion, which is small enough to enter your lungs and lodge in the lung walls. Once lodged all those combustion byproducts leach out into your body. Diesel vehicles need dust traps at the very least.

: Are there are projects in any of the consumer electronic-do-it-
: yourself mags?

There was a letter to the editor in Oct 15, 1990 "Electronic Engineering Times" magazine that had some hints on do-it-yourself magnetic field meters. Basically, you make a big pickup coil and hook it to an oscilloscope or RMS voltmeter. The pickup coil responds more strongly to high frequencies than low, with a 6 dB/octave response curve. So, to get accurate results, you follow the loop with a 6 dB/octave low-pass filter (series resistor, shunt capacitor). You can wind the pickup loop yourself (e.g. 1350 turns 5 cm diameter delivers 1 mv in a 10-milligauss 60 Hz field -- the author used a 47K / 0.1 uF de-emphasis network which results in .4 mV for 10 milligauss.) Or you can simply use a dismembered C-frame 115V motor, disassembled power transformer, or bulk tape eraser.

To calibrate the pickup, make a one-turn loop of wire 11 inches in diameter and feed .223 amps AC through it. That results in a 10 milligauss field at the center of the loop. A more uniform field can be generated with a Helmholtz coil, with a bit more work.

: I don't want to get into a debate about whether such testing is
: worthwhile (at least not now).

OK, but just to put the whole EM field scare in perspective, the fields from CRT's typically measure in the few (single-digit) milligauss range, which is comparable to the stray 60 Hz fields you would find in the average home. The field directly under a high-tension power line is typically a few 10's of milligauss, which is comparable to the field close to your average electric stove burner. The earth's magnetic field is about 500 milligauss.

I just saw a neat little book that contains a project very much like this. The title is something like _Amazing Audio and Video Projects_, by Carr and someone else. A TAB book, I think, so give them a call for the specifics. Fairly high-level projects with interesting background.

The CATV project is a home-distribution system, a kind of miniature home-CATV system. Modulate up various baseband video sources, stick them on your cable for use. Would be easy to modify for generic RF->RF translation.

: >it should have good (teflon) insulation. ...

: That actually sounds like a bad idea to me. Why not just use a lower voltage
: transformer? ...

: Inrush current limiting will only extend tube life in that it will reduce
: the chances of filament failures. Whether this is important or not depends
: on the particular tube type. Easy ways of handling turn-on filament failures
: are to use a slightly undersized transformer that is impedance-protected, or
: to use thermistors.

That's the advantage of using a resistor (or high-resistance wire) on the filament secondary: it reduces inrush current at turn-on. However, you can accomplish the same thing by adding a resistor in series with the primary -- it's usually easier because the resistor value is not so unreasonably small.

To measure the AC magnetic field of a monitor make a large diameter wire loop. The voltage induced in the loop conductor is propotional to (number of turns) X (loop area) x (dB/dt). Output voltage is directly propotional to the AC magnetic field frequency.

TV and monitor screens have magnetic deflectors. They produce a high-freuquency field (around 15 - 30 kHz) which is easy to measure with a suitable AC voltmeter and the loop antenna. The frequency dependendence of the loop efficiency will cause the TV deflection fields to seem to have a magnitude of 300 times higher than a 60 Hz magnetic field with the same field amplitude.

A simple RC low-pass filter (integrator) will have an attenuation coefficient of 1/f and can be used to make the field sniffer frequency independent. Follow that with an opamp gain block and an opamp rectifier circuit and you have a simple "Directional Enviromental Magnetic Field Detector".

Mitsubishi laser diode module FU-16SLD-N3. Infrared 1300 nm, peak power
4 mW, class IIIb. Mfrd 1991. New in original sealed anti-stat boxes.
Specs for a typical one pulled from the bin at random:

I(th) 13.5 mA
I(op) 26.8 mA
PL 0.22 mW
lambdaP 1293 nm
I(m) 0.409 mA

Diode is press-fitted into a handsomely machined stainless case which looks
somewhat like a 0.25" diameter chassis mount BNC, but with threads instead
of pins. (Probably a precision fiber socket of some type.)

Looking to get $8 each for these units (15 of them available).

597. Duplexer design info?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-12 23:23:53 UTC
From: n7oo@huachuca-emh8.army.mil
Message-ID: <199403122332.PAA14622@ucsd.edu>
Source record: 118387

In browsing various publications, appears modern VHF/UHF duplexer design is a product of the black art. I'm in the process of cutting down an old DB Products band-pass 2M duplexer for 220 MHz. This duplexer has coupling loops in each cavity. My references don't discuss whether there is an optimum coupling loop shape factor Vs frequency. Nor is anything mentioned whether the lengths of the cavity coaxial connecting lengths are critical. One commercial reference cautions field technicians from modifying the coaxial harness, stating to do so will cause deteriation of duplexer performance.

Whilst the cavities are apart, it would be nice to modify them for band-reject operation as well. Again, my references are silent on this topic.

Anyone on the net willing to share their practical experience/guidance about duplexer design?

>I suppose.

I'm afraid that appears rather typical of Rick. He does good designs, but
he services reader response only when he feels like it, which appears to
not be often. I had similar problems getting him to fullfill on the 902
MHz transverter kit. I eventually got it, but response time was slightly
over one year. (!) I advise getting the board templates from the ARRL
and proceeding on your own. (His designs really do tend to be foolproof,
it's worth the effort. The slow response I suffered may not be typical,
others I know have gotten much quicker service. I've built two different
transverters of his design. Both worked first time without any fooling
around. I've no doubt the transceivers will work as well. I'm intending
to hunt him down at Dayton and deal face to face for a couple of them.)

The harness is an integral part of the duplexer. For a band reject duplexer, the electrical lengths of the cables are integral parts of the tuned system. Altering them will grossly alter the behavior of the system. The cables are *slightly* less critical in a bandpass duplexer, but impedance matching is even more critical, and shielding is crucial.

A bandpass cavity has two ports, input and output, a band reject cavity has a single port. It behaves as a tuned stub with the harness forming a part of the stub. The idea is to have a pole zero at the thruline connection. Coupling loops really are a black art. Their shape, size, and position all interact to give the desired degree of insertion loss, impedance match, and passband shape. There are analytical methods of designing them, but most shops seem to rely more on cut and try methods.

Gary

Hi,
Has anyone here built the Ramsey Hobbykits' QAMP Tx amplifier with
the T-R reply? Any comments? What is the size of this thing and how well does
it perform? Tks.

73,
Daniel

606. home-built crystal filter - it works!

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-13 19:09:15 UTC
From: jjw@seastar.org
Message-ID: <CMMAJG.Cp@seastar.org>
Source record: 118396

Another progress report on crystal filter designing: As I did
not have the correct caps for an 8-pole SSB filter, I used some of the
extra crystals I'd matched to make a 2200Hz 5-pole Chebychev 0.1db
ripple filter. Results were quite good!
The design spec was for 2200Hz bw, and the result was 2240Hz
wide. It drops like a rock on both sides. Is 200 ohms in and out, so
I matched it with a 4:1 transformer on the input and a 200 ohm
resistor on the end.
I have not yet measured insertion loss, and the ripple looks a
little bit higher than 0.1db (like maybe 0.5db) using stock value
capacitors. I did no tuning at all, just used the closest stock value
caps I had, and it works well.
The program I wrote calculates not only the shunt caps, but
the series caps needed to re-resonate the crystals. These caps are
the important ones if you want the shape to be correct. Calculating
these by hand is a bit of a bear, but with a computer and BASIC it's
pretty easy.
Now to prettify the program and the output, get some more caps
and sling more solder...

The SL560C is a Plessey 300 MHz low noise amp.
- 14 dB gain with 300 MHz bandwidth
- 2 dB noise figure with 200 Ohm source (3.5 dB with 50 Ohm)
- 7 to 11 dBm compression point (1 dB), depending on supply
compression point drops above 30 MHz (6 dBm @ 300 MHz, 9 volts)

I have the data sheets for FAX or snail mail. Send me e-mail if you would
like a copy. There is also an 9 page ap. note which I do not have.

Thanks for your input on cars etc. so far.

I have narrowed my thinking to a small pickup or sport utility such as
Bronco, Trooper, etc., probably 86 to 91.

I am told that American cars have less solid state devices to go awry
due to RF from HF or VHF rigs, that Ford seems to be a good choice, that
Japanese vehicles may be more susceptible to RF.

Again, besides physical comfort (my back) criteria include lack of problems
from car to rig and vice versa, and other normal concerns.

All input welcomed. Thanks again. Bob

I am looking for information on a crystal/oven manufactured by James Knights Company. It is a 1 MHz rock mounted in an oven which operates at 55 C. The model number is JK5T.The heater runs on 6.3 volts and the volts and the unit plugs into a 5 pin socket. In the best of all worlds, I'd like to know the pin-out, the xtal cut and whether the xtal was designed for series or parallel operation.

In any case, does anyone know if the James Knights Co. is still in business? They were located in Sandwich IL when the crystal I have was manufactured.

I can help a little on the NEC device. The UPB571C is a dual modulus
pre-scaler rated up to 500 MHz. It offers the following ratios:

divide by 16, divide by 17
divide by 32, divide by 33
divide by 64, divide by 65

Input sensitivity is 400 mV,p-p and output amplitude is 1.2 V,p-p.
Supply voltage is 4.5 to 5.5 volts at 11 mA.

I don't have info on the pin-out.

I think it is manufactured by a division of NEC known as California
Eastern Laboratories. Here are some phone numbers:

(408) 988-3500
(408) 988-7846
(213) 645-0985

My '94 Chevy Lumina Euro seems OK for HF; I'd planted my Kenwood
TS-140 on the passenger seat the other day, and had NO problems.
75W out on 20M thru the cigarette lighter; OK, large capacitor and
ferrite torroid on power lines, left over from my '88 Grand Am whose
"Driver Information Center" didn't like the 20M band :-). Couldn't
even find the "birdies" from the Engine Control Module's uP!

The only discernable "noise" is a small bit of hash from the fuel pump,
and a lot of hash when raising/lowering the power windows. I suspect
a simple LCL Pi filter on the fuel pump harness (near the fuel pump)
would take out the noise, but so does the noise blanker on the radio.

BTW:
Not to make this a big sale pitch for GM, but we do a LOT of RFI
testing on our cars to make sure that they neither corrupt nor get
corrupted by ham rigs. Stop by the GM booth at the Dayton HamVention
and we can talk some more . . .

^^^^^^^^^^
! WRONG !

We've been building diesel engine controllers for many many years.

In fact, we've got an engine controller for LP-fueled fork-lifts!

And we've got a controller for marine applications; one of them even
got submerged (with the boat) in salt-water for 10 weeks, and after
they dredged-out the boat (and cleaned-up the engine) the engine
started on the 1st-crank with THAT controller. But I digress.

There are several diesel models with computers controlling the
electronically controlled transmissions!

And what about the instrument cluster, CD player/Radio, etc.?

619. adaptive denoising filters for voice

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-14 18:24:23 UTC
From: steve@hi.com
Message-ID: <steve-140394123659@brainiac.hi.com>
Source record: 118409
Cross-posted to: comp.dsp,rec.radio.amateur.homebrew

I'm interested in understanding the design of adaptive denoising filters for voice communications. There are several manufacturers selling DSP denoising filters to the amateur radio marketplace, and apparently some commercial units for aviation communications. Some well-known manufacturers are JPS Communications, Inc, Timewave Technology Inc, and W9GR.

Dr. Steven E. Reyer, WA9VNJ, and David L. Hershberger, W9GR published a brief tutorial in the September 1992 issue of "QEX", published by the ARRL. Their adaptive denoising filter uses Widrow's LMS algorithm to adapt an FIR filter, using a delayed version of the input signal as the reference signal. They claim that by proper choice of the delay and adaptation time constants, the FIR filter will adapt to a bandpass response around the portions of the spectrum which have a high "short-term" correlation (corresponding to the speech signal), and thus reduce the uncorrelated noise.

Reyer and Hershberger only reference Widrow et al's 1975 paper "Adaptive Noise Cancelling: Principles and Applications" in the Proc. IEEE Vol 63, No.2. I haven't tracked down this reference yet. (Wish I lived closer to a good university library.)

My questions:
1) Do the other denoising products use an algorithm similar to that described by Reyer and Hershberger? If not, what algorithms do they use?

2) Are there any good tutorial papers on this subject? Any important references other than Widrow et al?

3) It occurs to me that an LPC vocoder, such as used in a CELP vocoder, would serve as an effective denoising filter, since it supposedly models the vocal tract resonances. The excitation for the reconstruction filter would be the input (noisy) signal. Is it feasible to extract the LPC parameters from a noisy signal? Is anyone using this approach?

Thanks in advance for your time.

Regards,
-Steve

: This is true, but it strikes me as a rather inefficient method of going
: about it. Thermistors are cheap.

True, but transformers are not cheap. If you can use a surplus 6.3V transformer with a 6.0 or 5.0V filament, you might be able to save some bucks. And the dropping resistor gives you inrush current limiting for free.

Incidentally, many commercial amplifiers intentionally use a transformer that is almost under-rated, spec'd so that it puts out the required voltage only when under full load. The internal transformer resistance provides the inrush limiting function.

: There one more good reason to put a capacitor parallel with a power
: rectifier diode. Carrier lifetime in typical diode happens to cause
: fair amount of RF noise in the 1 - 15 MHz band. The noise is very sharp
: mains frequency pulses. About 1 nF ceramic capacitor parallel with each
: diode with very short leads takes most of this noise out. The curious thing
: is, that capacitors before and after bridge rectifier are not effective.

Good point. The other solution is, paradoxically, to use faster diodes.
Faster diodes have much shorter carrier lifetimes which prevent
avalanching of the faster diodes in the string caused by depletion of
the carriers of the slower diodes.

Gary Coffman (gary@ke4zv.atl.ga.us) wrote:

: Coupling loops really are a black art. Their shape, size, and position
: all interact to give the desired degree of insertion loss, impedance match,
: and passband shape. There are analytical methods of designing them, but
: most shops seem to rely more on cut and try methods.

The qualitative rule is: the bigger the loop the greater the coupling.
For bandpass cavities, more coupling results in less insertion loss,
but greater bandwidth. Less coupling gives a narrower bandwidth, but
more loss.

For band-reject cavities, more coupling gives a deeper, but wider notch.
Coupling also affects the tuning of the passband. If you want to convert
a 2-meter notch-type cavity to 220 MHz, I would recommend changing the
cavities to get the notches in the right place, then shrinking the
coupling loops to get the desired notch depth, and then playing with the
cable harnesses to get the passband right. There will be some interaction
between the three changes, but it should be doable. Be aware that some
of the better cavities have temperature compensation built in. Your
changes will likely defeat that feature.

Anyone have experience running a rotator with a power inverter?

The specific question is will one of the smaller rotors work with the
$100/200W units? Primary interest is use a backup power supply (marine
battery) for emergency services. I know that some of the cheaper
inverters only put out square waves. Does this cause a problem?

Thanks in advance.

The 1/8 inch mini jack on the 512, Plus, & SE is a speaker jack. When Macs started shipping with System 7 you got a mike input jack (cause you can record your own system sounds!)

A MacRecorder and associated software will do what you wanna do. Up to a 22Khz sampling rate, 8 bits quantization on each of those samples. Does waterfall displays, FFTs in real-time, as well as the old standby waveform display.

Has a line in jack and a mic jack. I got mine hooked up to a siesmometer (no it wasn't on at 4:20 AM, when the earthquake let loose).

My father uses a TS 50 and an IC901 in his taurus. only noise is slight alt whine on the 901. Only effect caused by xmitting is changing the speed of the key-in-ignition chime when xmitting on 440. He's happy with car.

Of course I hold onto my old 71 VW bus. Point ignition, generator, etc. all waay in the back, entire body grounded, lotsa room for rigs, etc. I'd hate to lose that car!

626. Capacitor code (NOT color code)

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-15 01:29:59 UTC
From: cravitma@cps.msu.edu
Message-ID: <2m332n$l53@msuinfo.cl.msu.edu>
Source record: 118416

Someone help!

I obtained a pack of about 500 disc capacitors, and they are all labelled with a code which I do not understand and have not found any reference for so far (ARRL handbook etc). For example, what _looks_ like a .1 uF capacitor is labelled "102Z".

Can someone mail me or post a translation of these codes?

BTW, I assume this is _not_ the tolerance coding, since there is only one line of this stuff and no other values printed on the capacitor.

Thanks.

Has anybody out there ever connected a TNC to a PRC-77 (manpack) or
RT-524 (veh mounted) VHF Military radio. I have to do just this and
would really appreciate some advice. I understand the interface is
nu as Mil-Spec as one would think.

Thanks
DAve

It's just like the resistor color code except it uses numbers instead
of colors. "102" means "10 plus 2 zeros" or 1000 pF. A 0.15 uF would
be "154" = 150000 pF = 0.15 uF.

I believe the "Z" is the tolerance. Probably Z5U.

Hi,

Need recommendation for a small TX amp kit which takes about 4 watts output from my QRP rig and puts out 20-30 watts with
built in T-R switching (preferably solid-state T-R) and runs off 12-13.8v DC power supply. Must be small so I can fit it into my
existing rig's casing. Should be something similar to the QAMP-20 from Ramsey Hobby kits. BTW, this is for 20 meters. Tks.

73,
Daniel

Changes: new mailing lists, .packet rmgroup, and .policy updates

(Note: The following is reprinted with the permission of the author.)

This message describes the rec.radio.amateur.*, rec.radio.cb, rec.radio.info,
and rec.radio.swap newsgroups. It is intended to serve as a guide for the new
reader on what to find where. Questions and comments may be directed to the
author, Jay Maynard, K5ZC, by Internet electronic mail at
jmaynard@oac.hsc.uth.tmc.edu. This message was last changed on 18 September
1993 to add the mailing lists for the new rec.radio.amateur newsgroups, to
note the rmgroup of rec.radio.amateur.packet, and to officially retire some
(in)famous threads of discussion on rec.radio.amateur.policy.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list
for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions
were held on the mailing list, and sent to the mailboxes of those who had
signed up for it. When the Usenet software was created, and net news as we
now know it was developed, a newsgroup was created for hams: net.ham-radio.
The mailing list and the newsgroup were gatewayed together, eventually.

As the net grew, and as packet radio came into vogue, packet discussion began
to dominate other topics in the group and on the list. This resulted in the
logical solution: a group was created to hold the packet discussion, and
another corresponding mailing list was created as well: net.ham-radio.packet
and PACKET-RADIO, respectively.

These two groups served for several years, and went through Usenet's Great
Renaming essentially unchanged, moving from net.ham-radio[.packet] to
rec.ham-radio[.packet]. Readership and volume grew with the rest of the
network.

The INFO-HAMS mailing list was originally run from a US Army computer at
White Sands Missile Range, SIMTEL20. There were few problems with this
arrangement, but one was that the system was not supposed to be used for
commercial purposes. Since one of hams' favorite pastimes is swapping
gear, it was natural for hams to post messages about equipment for sale
to INFO-HAMS/rec.ham-radio. This ran afoul of SIMTEL20's no-commercial-use
restriction, and after some argument, a group was created specifically
```

for messages like that: rec.ham-radio.swap. This group wasn't gatewayed to a mailing list, thus avoiding problems.

While all this was happening, other folks wanted to discuss other aspects of the world of radio than the personal communications services. Those folks created the rec.radio.shortwave and rec.radio.noncomm newsgroups, and established the precedent of the rec.radio.* hierarchy, which in turn reflected Usenet's overall trend toward a hierarchical name structure.

The debate between proponents of a no-code ham radio license and its opponents grew fierce and voluminous in late 1989 and 1990. Eventually, both sides grew weary of the debate, and those who had not been involved even more so. A proposal for a newsgroup dedicated to licensing issues failed. A later proposal was made for a group that would cover the many recurring legal issues discussions. During discussion of the latter proposal, it became clear that it would be desirable to fit the ham radio groups under the rec.radio.* hierarchy. A full-blown reorganization was passed by Usenet voters in January 1991, leading to the overall structure we now use.

After the reorganization, more and more regular information postings began to appear, and were spread out across the various groups in rec.radio.*. Taking the successful example of the news.answers group, where informational postings from across the net are sent, the group rec.radio.info was created in December, 1992, with Mark Salyzyn, VE6MGS, initially serving as moderator.

In January, 1993, many users started complaining about the volume in rec.radio.amateur.misc. This led to a discussion about a second reorganization, which sparked the creation of a mailing list by Ian Kluft, KD6EUI. This list, which was eventually joined by many of the most prolific posters to the ham radio groups, came up with a proposal to add 11 groups to the rec.radio.amateur hierarchy in April 1993. The subsequent vote, held in May and early June, approved the creation of five groups: rec.radio.amateur.digital.misc (to replace .packet), .equipment, .homebrew, .antenna, and .space.

The Current Groups

I can hear you asking, "OK, so this is all neat history, but what does it have to do with me now?" The answer is that the history of each group has a direct bearing on what the group is used for, and what's considered appropriate where.

The easy one is rec.radio.amateur.misc. It is what rec.ham-radio was renamed to during the reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize

this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, should be removed by September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is now rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there.

The first reorganization added two groups to the list, one of which is rec.radio.amateur.policy. This group was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The other added group is rec.radio.cb. This is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently Mark Salyzyn, VE6MGS. The email address for submissions to the group is rec-radio-info@ve6mgs.ampr.ab.ca. Inquires and other administrivia should be directed to rec-radio-request@ve6mgs.ampr.ab.ca. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas,

commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

On 15 Mar 1994 17:21:49 GMT, strange alien beings caused Keith M. Hamilton (ak238@yfn.ysu.edu) to write:

> I am going to be purchasing a DMM at dDayton this year. I would
> like to hear from someone who has had good liuck with a certain
> meter or perhaps someone who wishes they had bought a certain
> meter.
> I am a relative beginner to building and testing circuits and
> components and I would like to buy the best meter for the
> money.
> Thanks in advance for your help!
> --
> Keith M. Hamilton 73 de NO8Z

I have had a Fluke 77 for ~2 months and am quite happy with it. It is rock-solid durable, quite functional and easy to use. Some of the features I like are:

* Large, easy to read display
* Touch hold (locks measurement so you can put down probes and then read meter)
* Measures ACV/DCV/DC mA/Resistance/Diode Check/Continuity
* Good warranty
* Lots of accessories available

I paid about $150 for my 77, you will probably (especially at Dayton) be able to find one for less.

If you want more info about the meter, drop me a note.

Hi. I just got the March 1994 issue of 73, and I read an article on a
digital front panel for the TW-1 (Techno-Whizzy).

Apparently the TW-1 was a DDS VFO which was published in the December 1992
issue of 73.

I would really appreciate it if somebody would send me a xerox copy of
the article as I am interested in building it. I am also interested in
any other DDS projects that anyone else has come across, like the "Julieboard"
from 73 last summer.

oes anyone have any experience with these or other DDS projects?

thanks

634. ACS (Al's Circuit Simulator) version 0.13 is available

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-16 06:43:43 UTC
From: al@rbc.uucp
Message-ID: <1994Mar16.064343.2188@rbc.uucp>
Source record: 118274
Cross-posted to: sci.electronics,comp.lsi,comp.lsi.cad,rec.radio.amateur.homebrew

A new version of ACS (Al's Circuit Simulator) has been posted to alt.sources. It is also available by ftp from cs.rit.edu or ee.rochester.edu. (in pub/acs). If you don't have net access you can get it by dial-up from (USA) 716-272-1645.

ACS is a general purpose mixed analog and digital circuit simulator. It performs nonlinear dc and transient analyses, fourier analysis, and ac analysis linearized at an operating point. At this point the analog is stronger than the digital. (In fact, the digital part is rather weak.) It is fully interactive and command driven. It can also be run in batch mode or as a server. The output is produced as it simulates. Spice compatible models for the MOSFET (level 1 and 2) and diode are included in this release.

This version (0.13) includes several improvements including real Fourier analysis and better time step control based on truncation error. There are other minor improvements.

Since it is fully interactive, it is possible to make changes and re-simulate quickly. The interactive design makes it well suited to the typical iterative design process used it optimizing a circuit design. It is also well suited to undergraduate teaching where Spice in batch mode can be quite intimidating. This version, while still officially in beta test, should be stable enough for basic undergraduate teaching and courses in MOS design, but not for bipolar design.

In batch mode it is mostly Spice compatible, so it is often possible to use the same file for both ACS and Spice.

The analog simulation is based on traditional nodal analysis with iteration by Newton's method and LU decomposition. An event queue and incremental matrix update speed up the solution for large circuits.

It also has digital devices for true mixed mode simulation. The digital devices may be implemented as either analog subcircuits or as true digital models. The simulator will automatically determine which to use. Networks of digital devices are simulated as digital, with no conversions to analog between gates. This results in digital circuits being simulated faster than on a typical analog simulator, even with behavioral models. The digital mode is experimental and needs work. There will be substantial improvements in future releases.

ACS also has a simple behavioral modeling language that allows simple behavioral descriptions of most components including capacitors and inductors. Unfortunately, it is not well documented.

ACS uses an object oriented approach to modeling. Complex models like MOSFETS are made of simpler ones like resistors, capacitors, diodes, and any other models that may already exist. The model designer does not need to worry about details like convergence checking, bypass checking, integration, or how the new device plugs into the solution matrix because these are already taken care of by the basic models. This results in a dramatic improvement in the time it takes a researcher or model designer to install a new model, compared to Spice.

The source and documentation can be obtained by anonymous ftp from ee.rochester.edu or cs.rit.edu in /pub/acs. It can also be obtained by dial-up (USA) 716-272-1645 in /pub/acs. It may be distributed under the terms of the GNU general public license. The dial-up also has some test circuits, pre-compiled executables for Next, Sun4, MSDOS and possibly others, and documentation in dvi and postscript.

If you are tired of Spice and want a second opinion, you want to play with the circuit and want a simulator that is interactive, or you want to study the source code and want something easier to follow than Spice, try ACS.

ACS is an ongoing research project. It is being released in a preliminary phase in hopes that it will be useful and that others will use it as a thrust or base for their research. I also hope for some comments that may help me direct my research.

Cross-posted to: rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew

I have some TNCs and some baycom boards on my multiport Packet BBS.

I was reading through the manual for one of the TNCs (DRSI DPK-2), and it talks about a DCD board option that basically goes inbetween the TCM3105 chip and its socket.

Having DCD has shown itself to be nice with the Software DCD that the KPC-3 TNC does. I have problems with Intermod and frontend overload problems, etc.

Without having to buy the board itself, are there plans on how to build this DCD unit?

And, would anybody know if it would work on Baycom modems built around the same chip.

637. Crystal Filter Design program & details

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-17 01:05:04 UTC
From: jjw@seastar.org
Message-ID: <CMsB0H.2rG@seastar.org>
Source record: 118277

For the past week or two I have been figuring out how to
design crystal IF filters using the technique described in the May
1982 article in QST by Wes Hayward. Rather than duplicate his
circuit, I used my TW-1 DDS as the signal generator and read the
results with an oscope.
I matched a large pile of surplus 10MHz computer crystals
cannibalized from dead boards, and found (from about 60 crystals) 29
crystals that matched within 10Hz (my limit of accuracy in
measurement), and they also matched for 3db bandwidth, parallel
capacitance (as measured by my radio shack multimeter) and resistance.
Armed with this data, I wrote a simple BASIC program to
perform the calculations discussed in the article. As Wes also
mentioned the importance of re-resonating each section, I added in the
calculations for the series capacitors for each crystal to get them
all to resonate more-or-less at the same frequency.
I built a 5 pole Chebychev filter with 2.2kHz bandwidth, and
hooked it up (wrongly) to my analyzer (I didn't have the right
connector and the antenna in isn't 50 ohms). I got mediocre results,
due to improper termination. Tonight, I found the right connector and
re-ran the measurements.
With no tuning at all, using the closest stock capacitance to
the calculated values, I wound up with a 2.1kHz 3db BW. Ripple was
designed to be 0.1db, but I measured about 1db of ripple. The
insertion loss was measured to be 2.3db. The60:6 shap factor is 3.34.
It drops sharply on the low side, and is more rounded on the high
side.
I'd say it was a success, all in all. As I've had quite a few
requests for the program to calculate this, here it is. Have fun with
it, and I hope to be on the air with my own SSB unit some day soon.

Yes, but at a mere 18,000 pounds not many can afford such a car. Practically, I found the Cavallier reasonable RF quiet. Fiat Uno, too noisy. Diesels are definately better, they have a bigger battery too.

I have had several QSOs with people on 10 meters who were using converted
CBs. I have a CB sitting in my junk box and was wondering if it could be put
to use in the 10 meter band. Is there some service center I can send it
to have it done? Is it something I can do myself? (The CB in question is
a Cobra Model 19 Plus, manufactured in 1988.) In general, how hard is it
to do this (ie maybe easier on older model CBs)?

Enquiring minds want to know. :-)

TNX and 73,
Erik

Well, I have some capacitors that have 10M listed on them. I know
that the M is the EIA code for 20% tolerance but am having trouble
with the 10 part since if it were 10pF it should read 100. [I was told
the caps were 10pF.] I can't find a code anywhere with only two digits.
Underneath the 10M code were the EIA codes for temperature and the
code 1KV which I interpret to mean that it can handle 1 Kilovolt.

My prsumtion, based on the MANY capacitors I've run across, is that the "102" stands for 1000 pF (i.e. .001uF), where the "1" and the "0" are the value and the "2" is the multiplier (works just like resistor color code, but can be done in black ink only . . .)

As for the "Z", it's probably a tolerance.
Digi-Key sells Panasonic ceramic disks, and according to the part numbers listed:

"J" = 5%
"K" = 10% <-- most of the caps we use 'round here
"Z" = +80%/-20%
"M" = 20%

A .1uF would be a "104", i.e. 100,000pF or 100,000/1,000,000=.1uF
=====
"4"

: A quick and easy method to find the internal resistance of an unknown
: meter is to put a pot and power supply in series with it and adjust the
: pot for a full scale reading. Now put another pot across the meter and
: adjust it until the meter reads half scale. Read the value of the pot
: with an ohmmeter (out of circuit) and you'll have the internal resistance
: of the unknown meter.

Be sure the series resistor has a much higher resistance than the
meter, or the second pot will affect the total current significantly.

: The internal resistance of a meter is a function of meter type and
: meter sensitivity (obviously). In a moving coil meter, you can think
: of the movement as a motor stalled against a spring, and the resistance
: is a result of the motor stall torque against the spring.

In other words, just the resistance of the coil and connecting wires
(possibly with internal shunt...) But it's a good point that such
a meter is a motor--or generator. If you shake the meter (specifically
rotate it) it will generate some voltage (unless you shake it so hard
it falls apart inside ;-).

Just like English spelling rules, there's exceptions. If the pF is
100 or less the actual value is stamped on the cap.

Here's a neat way to measure capacitance: Use a 120VAC to 12VAC
transformer and place your unknown cap in series with a high-valued
resistor (megohm range) across the 12VAC and measure the voltage drop
across the cap. Frequency is 60Hz, compute Z = E/I, use Z formula to
compute capacitance (or inductance, too!).

Cheapest L/C meter in town!

73,
Jeff NH6IL

I've had no end of wierdness dealing with RG-58 and poor
quality connectors. When I changed all my SO/PL connectors to N and
changed my coax to RG-142 (teflon-same size as RG-58 and I used crimp on
N-connectors on it), my output power went from 80W to 110 W out of my 2m brick.
So rather than worrying about these adaptors, change to a more
reliable
system

Good point. The idea is that the series resistor and PS form a constant
current source, so the series resistor value has to be significantly
higher than the meter and shunt resistances. If you have an adjustable
lab supply that can be configured as a constant current source, you
can use that directly instead.

>: The internal resistance of a meter is a function of meter type and

>it falls apart inside ;-).

Well no, the stall current is different than just that which you'd
have with only the resistance of the windings and possible internal
shunt. Otherwise you could just measure the unknown meter with an
ohmmeter. That most assuredly won't give the correct result with a
moving coil meter. That spring in the meter is placing a real load
on the "motor" that's reflected in the apparent resistance of the
coil. The work of fighting that spring isn't free.

Hi all, I hv a Heath SB1000 (Ameritron AL80A), that I wud like to add QSK to.
ALl the QSK kits are a bit expensive for my taste, but I was wondering. Is it
just the speed of the internal relay that keeps this thing from being QSK? Afterreading
Richard Measure's (SP?) article in QST, if I just replace the internal
relay with a high speed vacum relay (Jennings) will I be able to run it in QSK
or are there other restraints. Tnks for any help you can give.

651. Circuit simulation software for teaching

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-18 20:32:58 UTC
From: sbbrown@magnus.acs.ohio-state.edu
Message-ID: <199403182032.PAA25744@bottom.magnus.acs.ohio-state.edu>
Source record: 118292
Cross-posted to: ieee.general,rec.radio.amateur.homebrew,rec.radio.amateur,sci.physics.electromag,sci.electronics

I'm conducting a survey about the use of computer programs for digital
and analog circuit simulation in ee curricula. I'd like to know what
software is being used at other universities, what platforms it's run on,
what level (undergraduate/graduate) students are using it, and what problems
other ee departments have had making this kind of software available for
instructors and students.
In particular, I'd like to know if there are fairly simple simulation
packages (say 20-50 gates or components) that will run under UNIX or X-windows,
or if there are DOS/Windows simulators that will run on a '286.
Here at the Ohio State University we've experimented with several
approaches, but none of them has been entirely satisfactory. There are
some very sophisticated packages available for our UNIX/X-windows
workstations that are suitable for the graduate level courses and
research, but haven't proved satisfactory for the sophomore level courses.
They have a lot of features that the beginning students just don't need.
There are simpler packages available for DOS, but we can't run them on
the UNIX workstations (there is a DOS/Windows emulation package, but it
emulates a 286, and the simulator requires a 386.) We are reluctant to
buy a lot of PCs, as the experience of other departments in the university
indicates that PC networks are harder to maintain than the present network
of UNIX workstations.

653. Parasitic oscillations, help!

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-19 18:22:39 UTC
From: asirene@ntuvax.ntu.ac.sg
Message-ID: <1994Mar20.022239.1@ntuvax.ntu.ac.sg>
Source record: 118293

Hi,

I am building a Ramsey kit QAMP-20, TX Amp with 20 watts output on 20 meters based on MOSFETS and I think I am experiencing
parasitic oscillations at VHF, especially once the MOSFET gets hot. Why does this take place only when its hot? When its cool, say
the first 20 seconds of keying, it seems ok but once the MOSFET gets hot, there goes the oscillations. Any ideas how I can fix
this? I am redesigning the PCB with my own layout, is this advisable? The original board is single sided but I am not sure if their
layout is well considered. The oscillations further cause the T-R relay to go beserk, understandably so. I am not too familiar with
MOSFET design so I don't know what to do exactly. Will appreciate any advice.

Source record: 118294

The only problem I can see about using old gear on packet is the switching time. You will have to make sure the delay is long enough to allow the rig to change over to transmit from receive. Also, it may take a fair amount of current in the PTT line; if so you will have to add a buffer. 73 DE K6DDX

>existing rig's casing. Should be something similar to the QAMP-20 from Ramsey Hobby kits. BTW, this is for 20 meters. Tks.

>73,
>Daniel

Daniel, if you stumble upon a small CB ampflier, you might try using it
with your 20 meter QRP rig. Many of these amps are very broad banded, if
sometimes somwhat dirty. I know of a local ham who sometimes steps up
his 5 watt Ten Tec rig to about 50 watts on 40 meters, using a CB amp.

Ramsey's designs tend to be pretty minimalist for their amps.
Not being familiar with this design, I would suggest the following.

1). If there is a resistor from the gate of the MOSFET to ground, place a ferrite bead over the gate end of the resistor and solder it back down.

2.) Make sure the all the lead lengths on every component are short as possible.

3.) Use more bypassing on the V+ feed, in theory there should be a coil through which V+ is fed to the transistor, place .001, .1 and 50-100 uf caps on the side where V+ is brought to the board. Wind the V+ connecting wire through a binocular balun once or twice.

4.) Knowing Ramsey, they have probably used a rather crude biasing arrangement, this may have to be changed. Again, without ciruit details, this is all I could suggest in that regards.

5.) Make sure the ciruit board is well attached and grounded to a slab of heat sink and metal chassis, depending on the construction. A continuous sheet of metal underneath an RF ciruit will do wonders for it.

6) What type of load is being used for testing ? Be sure that no problems exist there. Use a proper, non-inductive load rated for the power you will be using. Checks for any shorts or open conditions in the cables. Make sure you do not have any resin bridges between pads on the circuit board, clean off with alcohol.

I am sure there are other things to consider, with more details I could be a bit more direct in my suggestions.

After building the DEM432 RX and LO kits, I'd say I'm happy with the
results. Those chip caps are very tiny though. Good near-vision
is handy (or a good magnifying glass in my case :-)).

The PSK signal (435.91) from the FO-20 satellite is fairly strong without a
preamp and using an indoor antenna. I'm using the HR-2600 for the 28 Mhz out.

There were a couple of reviews about the DownEast kits in QST.

Thanks for the info. Does that mean that older part numbers, e.g.
1N400X, have been redesigned to be controlled avalanche? One last
question: If I look into a new, commercial HV supply, what will I
find? Do they even use multiple discrete series diodes commercially,
or just single HV assemblies?

: found the Cavallier reasonable RF quiet. Fiat Uno, too noisy. Diesels are
: definately better, they have a bigger battery too.

: Mike

18,000 ho ho, you've been reading the brochures ! Just decide on a few creature comforts, a radio other than the one that comes standard (unbelievably nasty) and you are talking a lot more dosh still. I managed to resist the temptation of the central heating boiler and freezer, but occasionally wonder about adding a winch. The headlamps are a bit lacking (remember Spike Milligan's landladies' light-bulb jokes?) so a pair of decent lamps is essential, and the lamp bracket needed is #200+ bull-bar shaped... these things are not much diffeerent to range-rover prices when you get to decent levels of equipment...

With a heavy trailer behind and a pair of large horses, it's true class shows.

The local RIS man has been given a Discovery with a pneumatic mast through the roof. He's as happy as the proverbial dog with 2 tails. they've bolted a 240v generator where the airconditioner pump would go.

Note for US readers, see lower photo on Feb QST cover to see one of these vehicles out for a little fun....

Cheers
David

665. Simple Tx/Rx?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-21 18:13:46 UTC
From: gsegalli@ic1d.harris.com
Message-ID: <Cn11B0.Hx2@news.ess.harris.com>
Source record: 118305

I want to build an RF remote shutter release for a camera.
The idea is to push a button on a transmitter and then have
the receiver short two wires to trigger the electronic
shutter of the camera. I need a max range of about 50' and
it would be nice to have the receiver fairly insensitive to
unwanted noise.

I have seen several designs for simple transmitters (CW, tone
transmitters, etc.) They are simple (just a few parts, with
coils I can wind myself), small and cheap to build. They seem
to have adequate power for this application.

What I havn't seen is a simple receiver circuit.
If you have any ideas/designs/schematics for simple receivers
or TX/RX pairs please email or post them.

Thanks,
Greg

There was an article in RF Design magazine about three years ago
(look in the Dec. 92 or Dec. 91 article index under "receivers")
about a very simple receiver. It was the receiver only, no data
processing. Nice to have some simple encoding to prevent falsing.

Also, if you are willing to buy, look in DigiKey: they now carry
a rx/tx pair with encoding, about $40 for the pair as I recall.
These include address encoding/decoding, like garage door openers.

Finally, you can pick up pager receiver guts very cheaply
sometimes: like around $10 for a respectable narrow-band FM
receiver. This will make the transmitter more complicated, since
it couldn't very well be just LC oscillator controlled.

etc.

Folk have posted about making shunts, but I haven't seen consideration about the damping in the meter after you put a shunt across it. Many times this isn't an issue at all, but be aware that if you put a short across a d'Arsonval meter (moving coil), the damping will become much greater; a shunt is nearly a short. This means that the meter won't respond as quickly as it would if simply fed a current. Some movements are built underdamped (oscillate a bit before settling in to the final indication), and these could actually be helped by a shunt. One way to get around excessive damping caused by a shunt is to add a bit of resistance in series with the meter, but the down side of this is that the shunt then must be higher resistance and will dissipate more power and drop more voltage.

It's possible to use the back EMF generated by the moving coil to characterize the meter's damping (or similarly, Q) and frequency, much as is done for speaker drivers. I doubt many hams would care that much about it, but for example the ballistics of a VU meter are pretty well defined, and people dealing with lots of meters do take things like this into account.

Get yourself a pair of cheap toy walkie talkies equipped with
a morse code key. Hack the speaker output of one of them to
feed into a 567 tone decoder tuned to the audio freq. of the
morse code beep, and use the 567 output to trigger your camera.
Then just push the morse code button on the transmitting HT
in order to fire the shutter. Then you don't need to build
either the transmitter or the receiver. Just hack 3 or 4 parts
into the cheap HT, which usually has plenty of room inside, even
the micro miniature kind. The cheap HT's are about $10-15 a pair
(or hit a garage sale), plus the tone decoder is around $2 in
parts. Alternatively, pay $1000+ for something similar from Nikon...

Hey everyone, I am looking for some information on how to retune the channel elements for GE Master II radios. (I guess these channel elements are also referred to as "ICOMs" i.e. they have the word ICOM written on top of them, anybody who is familiar with these knows what I am talking about.) Anyway, I want to order crystals for these things and retune them myself, rather than sending the channel elements in to be recrystalled for me. (I am hoping to save some money.....) I am hoping that someone out there can fill me a little bit more on how these things are tuned. I know that there are several small parallel lines on the back of the circuit board that are supposed to be used for varying the capacitance, but am not sure of exactly how to go about this. I don't want to have to cut and resolder one by one to see what happens... Looking inside the units that I have, none of these lines have been cut, they are all connected... Anyway, any help would be appreciated!!!

Thanks in advance! - JON

Please forgive the cross posting if you will.

I need a room for two for Thursday, Friday and Saturday night at Dayton.
We have one room at the Hampton House with the FRC, and want one more
closeby if possible.

CU at contest forum and dinner, FRC suite, hamfest etc.

Tnx Bob

Hello, all

I am looking for a phonepatche for my CB and 10 meter radios, just like one of a fellow ham.

This is a manual device, the size of a little box, atached to the phone and to the rig, and my friend told me it costed him about $50 U.S. Dlls., but I have not been able to find it anywhere, and would like to know if it is too dificult to build it at home.

How can I build this thing?
Some time ago, I posted this same question, and somebody told me it can be made from some kind of old telephone.

Muchos Thanks in advance

Excellent advice from Walt... I also have an SB-1000 (non-QSK) and would like to dispel the rumor that you can't use a non-QSK amp on Amtor or Pactor. I've been using it for over a year with perfect results. Granted, the relay klunking takes some getting used to. Almost had heart failure the first time I used it, but it survived and so did I. The SB-1000 leaves the HV on all the time, so you're only switching the bias on and off, and the antenna, of course. CW is a different matter. There you do need real QSK.

680. Info wanted: ICOM IC2A 2m HT

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-23 15:40:29 UTC
From: ed@fore.com
Message-ID: <Cn4JJH.1wv@fore.com>
Source record: 118220

I recently Purchased an ICOM IC2A 2meter Handi Talkey at a hamfest.
The orig synthesized HT with the thumbwheels on top for freq selection.
I Have heard that these were built like tanks, very rugged and easily fixable
if they break.

I am interested in general info: Output power, current drain, details of
external speaker & mike jacks, Schematic / service manual, power requirements,
do's & dont's to do with the rig...

The unit has a 120v base charger for nicad packs.
I got 1 small Nicad pack that works in the base charger and has
a coaxial plug at the top of it to accept vehicle power to power radio
& recharge nicads (I have tried this)

I got 2 extra battery packs for nicads/alkaline AA batts but they will only
charge in the base charger. They have no provision for external power to
charge / override the batts. Is there a circuit that can replace the batts
and provide external power directly to the rig.

Will this unit work better at 12.5v than it does at 8.5v? Will it smoke at
13.8v?

Any and all info would be appreciated.

Thanks.

Ed Bathgate

Ronald Viegelahn (ron@etch-eshop.Berkeley.EDU) wrote:

: Hi,

: I keep hearing the term " third order intercept " when speaking
: of frontend intermod problems.

To further enhance your confusion... The voltage out vs voltage
in 'transfer curve' can be modelled fairly well with a power
series:
Vout=A1*Vin + A2*Vin^2 + A3*Vin^3+...
Ideally, A2,A3,A4,... = 0 and A1 is just the gain. But in
reality A3 is large enough that if you input 2 tones they
will beat against eachother and you'll wind up with 4 tones.
If you dig out a table of trig identities and substitute
V1*cos(2Pi*f1*t)+V2*cos(2Pi*f2*t) in for Vin you'll
see the terms 2*f1-f2 and 2*f2-f1 fall out. Other tones
fall out too, like the 3rd harmonics, but these are usually
out of band. If V1 & V2 are large enough the 5th order
terms 3f1-2f2 & 3f2-2f1 will pop up too and you'll have
2 more spurs show up. Usually the even order
terms are insignificant since most linearities are symmetric
and the spurs they produce fall out of band.
3rd order 2 tone spurs usually are the limiting factor in dynamic
range calculations and are the bane of RF engineers.
spuriously,
Art.

Hi Everyone.

I'm looking for advice from someone knowledgable in radio and electronics.
A normal f.m radio recieves up to about 108 Mhz.
Does anyone know how to adjust it to recieve from 108 to about 130 Mhz?
These are the aircraft frequencies and it'd be cool to listen in. I've
heard that it's quite a simple operation involving a small adjustment in
any cheap f.m reciever.
Any advice is very welcome. Remember I'm a very non-specialist audience
here, so please keep it simple.
I'd appreciate mail in this regard.
Thanks-

Well, adjusting the frequency upward is fairly easy, but the
catch is that aircraft communication is done on AM, not FM.
Still, you could add a simple diode detector to the output
of the last i.f. transformer and go from there. To adjust the
frequency upward, probably the easiest way is to find the coils
for the RF amplifier and oscillator and spread the turns out
a ways. Another problem is that the bandwidth of the i.f.
for regular commercial FM is about 100 khz - what you need for
AM is only about 6-10 khz or so. What this means is that you'll
be hearing several stations at once.

The best solution would be to get a radio made for aircraft, but
tinkering is fun too!

Good luck...

You can qsk with the jennings relays but you need some control circuits to
prevent hot switching. If you find a diagram of an old alpha 77 that is
exactly the scheme they used. 73 Bill AA5ZQ

Check out my article in Feb. 93 QST "Everything You Always Wanted To Know About Computer-Controlling Modern Radios" (I didn't pick the title :). It has plans for a Kenwood interface that is opto-isolated and implements the handshaking lines as well as the data for complete compatibility.

I also still offer the parts kits listed at the end of the article. Prices are the same, ($47 for Kenwood kit, $44 for Icom/Yaesu/Ten-Tec) but the address is now:

CW Technology
7328 Timbercreek Court
Reynoldsburg, OH 43068-1181

COD Orders Only (add $5) at 800-547-7479

The kits include PCB and all board mounted parts. You provide case and 8-15V supply.

NOTE: ARRL has the PCB layouts and the parts are readily available - you do not have to buy anything from me.

E-mail if you need more info

: transmitters, etc.) They are simple (just a few parts, with
: coils I can wind myself), small and cheap to build. They seem
: to have adequate power for this application.

: What I havn't seen is a simple receiver circuit.

If you only need one (as opposed to manufacturing thousands), try a radio-controlled car transmitter/receiver/servo. I use one for kite aireal photography, and it works well. You only need one servo, so a 2-channel radio is more than enough. Look for ads in RC car/airplane magazines. Or better yet, buy a used RC car, and head down to the local hobby store for one extra servo. The extra servo goes on the camera, and you can move the receiver between the car and camera. Twice the fun for your money...

An umbrella, a can of polyurethane varnish and a bit of ingenuity should
be a good start. Apply many coats of varnish to the umbrella to make it
a bit more reflective to sound, and fix a micrphone to the shaft at about
the focus. Of course this may not work at all.

Basically, the reflector will have no effect on sound of wavelength on the
order of its diameter or greater. Thus an umbrella might be expected to have
some effect down to, maybe, 500Hz. This is just about OK for intelligible
speech. However, the fabric will not be sufficiently reflective unless
treated - it basically needs to end up with a smooth, hard, rigid surface.

As for the choice of microphone, I suggest a shotgun of the type used for
ENG and interview work, with a good windshield, and roll of as much as
possible below 300Hz.

For twenty quid more than the price of the microphone this has got to be
worth a try. I have no idea whether it will be suitable for your applica-
tion as you don't give any details - like RANGE, for example...

692. RF VHF/UHF Preamp Design Params.

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-25 15:44:26 UTC
From: boley.d%wec@dialcom.tymnet.com
Message-ID: <boley.d-250394114011@129.228.248.65>
Source record: 118232

If you read articles on the construction of RF preamps they
spen words on bypassing & shielding and claims of gain and
noise figures. What they do not say is what contributes
to these claims. Is it the tap point on a coil, a bias resistor,
obviously the device, or is it some arcane combination.

The ARRL Handbook has several preamps for home construction.
The text mentions several transistors and some coil variations.
It never explains how to "tune" the peramp for best gain and/or
noise figure and the relationship to the various active devices.

I would like to build a basic preamp and start "playing around".
However, I would like to have some reasonable expectations on
what to play with and what to expect. Any source for info in'this area ??

A mighty poor one, though. First, an AM detector usually makes a lousy
product detector (hey even if it's just beeps, it should sound good); second,
you have a 6Kc bandpass instead of 3Kc, for twice the noise.

695. Build own Solid-State linear?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-26 02:02:10 UTC
From: gene@uicsl.csl.uiuc.edu
Message-ID: <2n0532INNmuf@roundup.crhc.uiuc.edu>
Source record: 118235

I'm seriously thinking of building a high-power solid-state linear with
10 Power MosFets....serious enough that I have just ordered ten BUZ-76A
MosFets from Computer-Component-Source, Inc...1-800-356-1227...at $3.99 ea.
They are 400 volt, 3A (9A peak), 40W units....I only have specs on the
"76"...I hope the "76A" doesn't add any undesireable spec. Input cap=420pf
output cap=60pf, reverse cap=25pf, TO-220AB case, etc. I'm hoping to keep
it as simple as possible. Someone please warn me if I'm too naiive, but
I'm considering using them in push-pull, parallel...five vs five. Even
if the input capacitance is swamped with as low as 10 ohms from each section
to ground (RF ground, because a little forward bias is required), only 20W
would be required to drive them to saturation (10vrms across either 10 ohm
to each of the push-pull inputs). This push-pull drive is easily obtained
by passing the output of the single-ended transceiver, thru a choke-balun
which converts the unbalanced transceiver to a balanced push-pull to the
MosFets. I'm thinking of using a center-tapped plug-in inductor for the
push-pull output from the drains....160, 80, 40meters. Even on 40 M the
capacitive reactance would net about 150 ohms across the tank-coil so that
a Q of 10 or 12 would yield a Z of about 1K or 2K which sounds reasonable
to me (could use some tips calculating this.....I plan to full-wave rectify
my household 230 volts...115-0-115 providing a very stiff 160 volt, 10 amp
supply, to apply to the center-tap of the output coil.....probably using
a small parallel-resonant "trap", one for each band..probably #16 wire for
heavy average currents...to keep thed RF from the 160v power supply.
Another choke-type balun on the output drains to convert push-pull back
to unbalanced, followed by any pi or L-matching networt required to match
the 50 ohm antenna, or provide extra harmonic filtering.
Plan to bias MosFets in class AB for minimum cross-over distortion.
I would hope to not have stability (self-oscillation) problems on these
low-frequency bands...perhaps a small amount of "cross-neutralization"
would be useful..the circuit could accommodate that very easily.
One motivation for wanting a solid state linear, even though I have a
600W vacuum tube model now, is that in many group situation QSO's you find
that your linear is in standby for most of the time over a several-hour
period, but actual transmitting may be on a very few minutes.

In general, low noise transistors have the most beneficial effect at higher frequencies. If your RF amp is working at about 10 MHz or less, you probably won't notice much improvement. Above that, a simple test is to listen to the noise with the antenna connected, but no signal present. Disconnect the antenna and see if the noise drops. If it does, then the limiting factor is the noise from the antenna, and not the noise generated in the front end transistor. If it DOESN'T drop, then a lower-noise transistor is called for.

You can get real fancy with noise figure measurements if you want, but for ordinary ham purposes, this test will tell you what you want to know.

Hi,

COncerning the 20m receiver noise article I posted earlier, I have now determined the source of that noise to be the MC1350 IF post filter amplifier. Can anyone suggest anyway to quieten this very noisy part?

At the input transformer a 200 ohm resistor is set in parallel and at the output, a 1k in parallel with the output transformer. Both input's and outputs are in balanced configuration.

Would appreciate any advise on this MC1350 noise. Is there any other component I can use in its place which would lower the noise. It appears as a background hiss (white noise) and since it is post-IF filtering, it is quite audible and irritating though not worse than the atmospheric noise.

I am aware of atmospheric noise conditions but I ask this not because the present situation is unbearable/unusable but I'd like to IMPROVE the system as far as possible. SO regardless of whether this is going to provide any benefit in practice, I'd like to understand the theory at least, for getting rid of the noise from the MC1350. Of course I know that filtering or adding a filter helps but that does not deal with the noise source, merely cuts it out.

Tks. in advance.

73,
Daniel

703. Re: Build own Solid-State linear?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-27 17:59:29 UTC
From: gene@uicsl.csl.uiuc.edu
Message-ID: <2n4hi1INNr7i@roundup.crhc.uiuc.edu>
Source record: 118243

A correction to output-Z mentioned above...someone correct me if I'm way
off on this corrected output-Z estimate: from a typical family of curves
suggested for the BUZ-76, it appears that the Drain voltage would swing
between 160v and 5v, with a peak current of about 11 amps for a peak
power input of 1760 watts. According to an example I saw in an old "Radio
Handbook" showing an example of two 811A's for push-pull audio...this
155v/11a =14 ohms gets multiplied by four (2:1 voltage gets squared to
4:1 impedance)..yielding an output-Z of 56 ohms! Does this seem to be
a valid estimate? If so, a the simple choke-balun will convert this from
balanced 56 ohms (drain-to-drain), to unbalanced 56 ohms (coax to antenna).
Some additional harmonic filtering might be desireable, but if you are
using a compact Hi-Q loop, this is probably not necesary. On 160 meters,
it appears that the D-D capacitance would be about .013 ufd (Xc of 6 ohms)
for a Q of 10. This needs to be high-current....I have 13 .001 ufd micas
in parallel that I plan to use. The small uH inductor should probably be
1/4" copper tubing.
Any informed suggestions or criticisms would be suggested before I
invest too much time into an ill-conceived project! I plan to mount the
MosFet Drains directly to two separate large heat-sinks...elevated to carry
the 160v supply voltage. Hi-current blocking capacitors would be required
to isolate the 160v from the antenna output, BUT, I WONDER if #12 electrical
wire inserted inside the 1/4" copper-tubing inductor would couple out the
power suitably, avoiding the need for D.C. blocking??? Any opinions?

705. IC 2A

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-28 14:04:00 UTC
From: HICKS.ALAN@epamail.epa.GOV
Message-ID: <01HAI2TP4OMQ8X30NS@mr.rtpnc.epa.gov>
Source record: 118245

Hi, Ed - I've got an IC 2AT - same radio, but with the touch-tone pad option. If you'ld like a copy of the owners manual and a schematic, I can put one together for you. The BEST way to power the rig externally from 12-14 vdc is an adaptor called the DC-1, I believe, which converts 12-14 vdc to about 9.6 VDC and runs the transmitter at about 1.5 to 2 watts. The maximum safe voltage for the unit appears to be about 10 volts - I think the BP-5 (a high-power drop-in charge power pack from ICOM) is maybe 10.8 volts. Twelve volts or higher applied directly to the battery input terminals will probably smoke the radio, so don't do it. If you can't find the stock DC adapter, you can build one from an old BP-2 or BP-3 battery pack by wiring in a simple voltage regulator circuit and a protective fuse. Make sure you get a 10V regulator - they're a little rarer than than the usual 12 v ones.

One of my favorite replacement battery packs for the 2A is a Delcom pack available from TNR, W&W and other battery stores. This pack holds 8 standard AA NiCds and has the built-in charging circuitry similar to that in the ICOM's own BP-3 type batteries. You can keep a spare set of charged NiCds and snap them in when the first set runs down. The price with A set of AA's is around $27. It's a little more fragile than an ICOM-built pack, but it lasts a long time on a charge. I hope this helps. Let me know if you need the manual and schematics. 73 de KD1DJ, Alan.

: in the RSGB VHF/UHF manual and the ARRL microwave experimenters
: manual. Does anyone know of cookbook filter tables for filters
: of this type? As a last resort, does anyone know the process
: for scaling down the 10GHz versions?

Volume 2 of the Microwave Hanbook by the RSGB might have
what you want. Problem is, they describe iris coupled filters,
which I find harder to build than post coupled filters. Though,
if you want to use up little pieces of waveguide, I've found that
you can indeed use them up making an iris coupled filter.

A useful reference appeared in the 1948 Bell System Technical
Journal by W.W. Mumford Maximally-flat Filters in Waveguide
p.684- I recall it had a pretty good explanation of what is
going on--but its been 7 years since I studied it...
I'd venture to say that someone who fully understood the
math in this article would be able to scale 10 GHz versions.

This is still available from A and A Engineering.

A difficulty with this project is that the spectral output probably
isn't acceptable for anything but the most casual receivers--spurs are
in the -55 to -60 dBc range. Newer chips do better, but still aren't
good enough for high performance receivers unless you are willing to
filter the output with a tracking filter. A well designed PLL is
commonly used as a tracking filter.

It might work for a while, but you're putting 120 volts on a winding
designed for 40, and 400 volts on a winding designed for 120. Not good.
A good source of cheap but good transformers is Fair Radio Sales in
Lima, OH. I don't have their # handy, but information will. They will
send you a great catalog - all kinds of surplus goodies.

If you're willing to do some scrounging, a transformer from an old
tube-type color TV would do the job, too. They were built for
continuous use and in my 18 years in the TV service biz, I never saw one
fail - quite a remarkable record! They come in two flavors: bridge
rectifier output and voltage-doubler output. Either one will give you
about 400 volts DC at about (I'm guessing here) 200-250 ma, plus the
voltage-doubler kind can be used with a bridge to give you half the
voltage at twice the current.

716. Semiconductor specs and equivalencies

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-29 05:29:39 UTC
From: jwelch@acsu.buffalo.edu
Message-ID: <CnEv9G.K9H@acsu.buffalo.edu>
Source record: 118256

Dear Net:

This seems like the relevant area to post since it is likely to be read by both amateur and professional electronics people who work hands-on everyday with semiconductors of all sorts, if another group would be more appropriate, please email me.

Question: Is there a resource which one can consult, preferably online, to get design specifications on semiconductor components and to determine equivalencies between components for purposes of substitution?

I am familiar with semiconductor catalogs which list chips from each manufacturer, but this seems like an archaic way to go about searching. In addition to the awkwardness of thumbing through these tomes, it would seem too expensive to maintain libraries of these catalogs and keep them up to date.

I am interested only from the perspective of a hobbiest trying to maximize the utility of his junk collection. There are several projects I would like to try, but years after the projects have been written up, parts numbers change, better substitutes come out, etc.

This must be a general problem, and I apologize if it is in a faq of some sort. If this is a question of general interest, please respond via this newgroup. Otherwise, I can be contacted by email to: welch@sc3101.med.buffalo.edu

Thank you for any responses,
Sincerely,

John J. Welch

I wouldn't recommend it--the one of the limiting factors with high voltage transformers is voltage breakdown across the insulation. However, you can run a pair of transformers back to back--say a 115 to 12V and a 12 volt to 240 volt. Hamfests are pretty good sources for cheap high voltage transformers--if you stay till the end of the event you can often get them for free :-).

I have had a FLUKE 77 for about 9 years now and has survived a lot of abuse.
I was working at this institute as a lab technician and used it for classes and
work for about 5 years and only had to change the battery twice (left it on).
One guy borrowed it and tried testing current from the wall socket by plugging

the leads in with out a test circuit. It melted the tips off of the probes but did no damage to the meter except blow the fuse. It is one rugged meter and I will never consider another one as long as it is going. (which seems to be forever).

Steve,

I have made a number of WG filters for X band using the companion
software to ARRL's "Microwave Experimenter's Handbook". (The software
disk costs money and does not necessarily come with the book.
Consult a ham bookstore list for details). The handbook discusses
simple ways to do the machining with inexpensive hand tools.

Your requirements spec'd above are a snap for a simple inductive iris
WG filter design, and I think you will have no problem at all.
Construction is fairly simple, except that insertion loss is
affected considerably by how much flux and solder you accidentally
get inside the cavities. I have switched from simple solder sweating
to silver brazing. This requires real (98%) silver solder and
about 900 degrees F. It is nice that the boric acid flux is soluble
in hot water, though.

The program I use is called WEFILTER.BAS, the documentation for which I
have
reproduced below.
------------------ BEGIN wefilter.doc ----------------------
"WEFILTER.BAS": WAVEGUIDE FILTER DESIGN

The usual lumped-element filters are difficult to realize and tend to be
exceedingly lossy at microwave frequencies. On the other hand, waveguide
filters are relatively easy to build and are nearly lossless at microwave
frequencies. This program provides the necessary dimensions for the
construction of a waveguide filter given the desired filter response.

The program (written by M. H. Walters, G3JVL) first asks for the number of cavities, center frequency and bandwidth. The filter will have an equal-ripple response in the passband. This means that the filter passband is not flat but rather smoothly ripples from zero attenuation to some small value and back again. The number of points with zero attenuation (also called "poles") is equal to the number of cavities. The filter below is designed for 0.25-dB ripple. The bandwidth specified is the equal-ripple bandwidth. For a 0.25-dB equal-ripple filter, the equal-ripple bandwidth is defined between the points where the response falls off to 0.25 dB. Note that the 3-dB bandwidth definition (where the response falls off to 3 dB) will label a given filter with a wider bandwidth. If you can tolerate more passband ripple (say 0.5 dB), you can get more stop-band attenuation. If you don't need a lot of stop-band attenuation, then you can design a filter with less passband ripple.

If you specify a negative number for the maximum passband attenuation, the program will ignore the value of the attenuation and give you a maximally flat, or Butterworth, response. At band center, the response is as flat as possible and there is no ripple. The tradeoff is that the skirts of the filter (stop band) do not fall off as quickly and the filter response at the band edges is more rounded.

Next, you are asked for the thickness of the iris. This thickness will change the filter response slightly and is taken into account. Then the appropriate rectangular waveguide is found for constructing the filter. Next, the program prints out values for the low-pass prototype. These values (and the B(I)/Y0, the iris susceptances) are not needed for filter construction. Opposite the iris susceptances are the diameters of the iris holes. For a three-cavity filter, four irises are needed. Note the symmetry in the listing. Also, the irises should be centerd in the waveguide. Finally, the length of each cavity (distance between irises) is listed.

The final part of the program explores the filter response. While it states that stop-band attenuation is calculated, it can also be used to explore the

passband. It can be interesting to view the equal-ripple band-pass response
and to check the definition of equal-ripple bandwidth.

In constructing the filter, you may want to add tuning screws, especially if
you are designing a narrow bandwidth filter. These are best added in the
center of the wide side of each cavity.

Also, keep in mind that any filter made from transmission line is likely to
have additional band-pass responses at multiples of the center frequency. Thus
they will have difficulty stopping any harmonics.

FWIW, I sent Steve design data for 3 section maximully flat and
3 and 4 section .1 dB Chebychev post filters in WR-137 guide.
Filter lowpass prototypes came from the MY&J tables and the post
diameters and spacings were generated using the same coupling model
used for the 10,368 MHz, 100 MHz bw filter I showed in July 1987 QEX.

: and power handling characteristics were correct? For example, using a
: 120v -> 40v transformer the other way 'round to produce 120v -> 400v.
: Just an idea,

First, it would be (a bit below) 360 volts, not 400.

But the Much Bigger Problem is that the transformer would get very hot and not last long under these conditions if it had been designed reasonably for 120->40 service. You would be applying 3 times the voltage to the 40 volt winding that it was designed for. Likely you would be running the core to saturation, and the current would be quite high even with no load on the secondary. You would get very significant losses in both the core and the copper.

You can test this out if you have a Variac and a reasonable AC current meter. Apply 40 volts to the 40 volt winding, and measure the current. Run the voltage slowly up and note what happens to the current. Do this all with no load on the "secondary". If you can monitor the phase of the current, figure the power dissipated as a function of applied voltage; if you can look at its waveshape, see if it stays sinusoidal... Don't go too far, or you will destroy the transformer.

Another potential problem is insulation: the higher voltages could exceed the insulation capabilities of the transformer. You'll probably run into the core-saturation limit before this becomes a problem, but it's worth noting.

Yes, it's kinda sad that it's so hard to find medium size power transformers for tube applications. Are any old tubed TVs being junked these days? Some have power transformers.

723. Building Hi-power Solid-State Linear

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-29 17:50:06 UTC
From: gene@uicsl.csl.uiuc.edu
Message-ID: <2n9pofINNapv@roundup.crhc.uiuc.edu>
Source record: 118263

(This previous posting got fouled-up so I will resubmit it since it
relates to a follow-up that is currently posted):

I'm seriously thinking of building a high-power solid-state linear with
10 Power MosFets....serious enough that I have just ordered ten BUZ-76A
MosFets from Computer-Component-Source, Inc...1-800-356-1227...at $3.99 ea.
They are 400 volt, 3A (9A peak), 40W units....I only have specs on the
"76"...I hope the "76A" doesn't add any undesireable spec. Input cap=420pf
output cap=60pf, reverse cap=25pf, TO-220AB case, etc. I'm hoping to keep
it as simple as possible. Someone please warn me if I'm too naiive, but
I'm considering using them in push-pull, parallel...five vs five. Even
if the input capacitance is swamped with as low as 10 ohms from each section
to ground (RF ground, because a little forward bias is required), only 20W
would be required to drive them to saturation (10vrms across either 10 ohm
to each of the push-pull inputs). Actually, with 5 MosFets in each section, they would only
need to be driven to 2A each. This push-pull drive is easily
obtained with a 1:1 choke balun...or perhaps a 4:1 stepdown,
by passing the output of the single-ended transceiver, thru a choke-balun
which converts the unbalanced transceiver to a balanced push-pull to the
MosFets. I'm thinking of using a center-tapped plug-in inductor for the
push-pull output from the drains....160, 80, 40meters.

I plan to full-wave rectify
my household 230 volts...115-0-115 providing a very stiff 160 volt, 10 amp
supply, to apply to the center-tap of the output coil.....probably using
a small parallel-resonant "trap", one for each band..probably #16 wire for
heavy average currents...to keep the RF from the 160v power supply.
Another choke-type balun on the output drains to convert push-pull back
to unbalanced to match
the 50 ohm antenna.
Plan to bias MosFets in class AB for minimum cross-over distortion.
I would hope to not have stability (self-oscillation) problems on these
low-frequency bands...perhaps a small amount of "cross-neutralization"
would be useful..the circuit could accommodate that very easily.
One motivation for wanting a solid state linear, even though I have a
600W vacuum tube model now, is that in many group situation QSO's you find
that your linear is in standby for most of the time over a several-hour
period, but actual transmitting may be on a very few minutes.

I don't have any knowledge of an online source, but one very good reference for mystery parts are the NTE, ECG and SK catalogs/cross-reference guides. These guides will cross-reference just about any semi you have to an equivalent (or slightly superior) device, and you can read the thumbnail specs on that device in the guide. You soon learn some of the part numbers by heart (e.g. the NTE 123A is your basic 2N3904/PN2222/etc). These guides cost $3-$4 and are readily available. Of course, the more exotic the device the less likely it is to be listed, but for hobby purposes we're generally using more common, available devices anyway. Another point to be aware of is that the equivalent devices may have slightly better specs than the device you're looking up (higher voltage, higher gain, etc). This might get you into trouble if you cross-reference desired part AAAA to (e.g.) ECG part BBBB and find that the BBBB is also the cross for a part CCCC, which you just happen to have. The CCCC may not be as "good" as the AAAA, depending. Most of the time, though, you should be OK.

BTW, I think some of these companies now have their cross-references on disk also.

A related question -

If one has a transformer without any labeling,
what is the best way to figure out how much
current it can handle at its various voltages?

If I take a transformer out of a piece of
equipment, I try to note the tube compliment
so I can add up the maximum current values from
the data in a tube handbook. However, this may
end up being a high estimate. I also have
lots of other transformers that literally came
from the trash without any manufacturer's model
numbers or other identifying data - or even any clue
what sort of equipment they came out of.

Thanks for any suggestions.

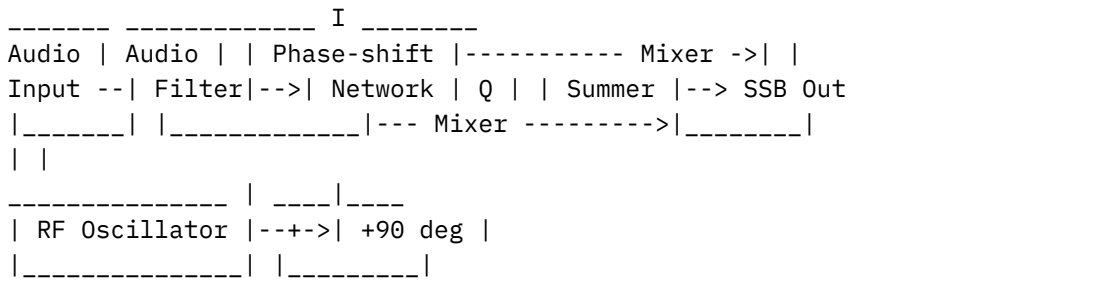
728. How phasing SSB Exciters Work (Was: RF and AF speech processors)

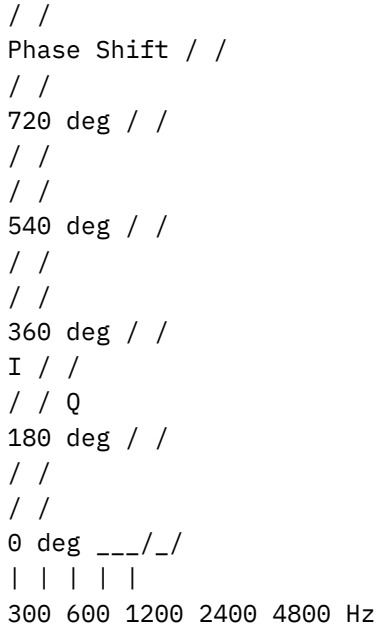
Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-29 21:26:17 UTC
From: alanb@sr.hp.com
Message-ID: <CnG3Jt.Htw@srgenprp.sr.hp.com>
Source record: 118168
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.equipment,rec.radio.amateur.homebrew

In another thread, I claimed that phasing-type single-sideband generators sound better than filter-type generators because phasing exciters have flatter amplitude and delay response. Gary Coffman disputed that. Rather than respond to Gary's long replies in detail, I'll just summarize how phasing-type SSB exciters work:



I and Q are two audio outputs with a constant phase difference between them of 90 degrees. The input filter limits the audio frequency response to the range of the phase-shift network. The "+90 deg" box can be switched to -90 degrees to get the opposite sideband. (The output of each mixer is a DSB signal.)

The audio phase shift network is the interesting (read difficult) part of the system. It must maintain a 90 degree phase difference and excellent amplitude matching between the two outputs over something like a 10:1 frequency range (300 Hz - 3000 Hz). It generally does that by causing each of the two outputs to have a constantly-rising phase shift versus frequency characteristic, like thus:



Frequency

I may have gotten the scaling off a bit, but the principle is right:
Both channels have constantly-changing phase shifts, but the difference
is always 90 degrees. Note that the frequency scale is logarithmic.
If phase were linear with frequency, then that would equal constant
delay. Since that's not true, there is some variation in group delay
with frequency, but it is a nice smooth curve that has little affect
on audio quality. (As opposed to the crystal filter used in a filter-
type SSB generator which has "bumpy" group delay, expecially at the
high and low band edges.)

The design of the two channels' phase-shift networks is such that
any errors in linearity occur in different places. That means that
you can't make it work properly unless both channels have nice
linear phase versus log(frequency). The same goes for amplitude.
I suppose you could design a diabolical phase-shift network that
had unflat (but matched) frequency response in the two channels,
but why would you do that?

The input audio filter can also add to amplitude or delay distortion.
However, it's not hard to design the filter to minimize the problem.
You don't need the sharp cutoff of a crystal filter designed for
receiving applications because any spurious below 30 or 40 dB down
will be covered up by the transmitter power amplifier's splatter
anyway. Also, audio filters are easier to build accurately than
crystal filters because of the lower Q and lower frequency.

The conclusion: Phasing-type SSB generators have flatter group delay
and amplitude than filter-type generators. You really can hear the
difference in the on-the air signal, in my experience.

Gary Coffman (gary@ke4zv.atl.ga.us) wrote:
: In article <1994Mar26.201156.9246@arrl.org> zlau@arrl.org (Zack Lau (KH6CP)) writes:
: >SSB crystal filters are designed for steep skirts for good
: >shape factors. This means that without any equalizing networks
: >(which normally double the complexity and send the cost through
: >the roof), the phase response at the passband edges are *terrible*
: >The fact that the center frequency of the crystal filter is much
: >higher just means that the Q of the parts has to be that much
: >better. The mathematics of the phase and amplitude response
: >tradeoffs are unchanged-- the tradeoffs are identical for a
: >3 kHz audio filter and a 3 kHz SSB filter (assuming ideal
: >parts--with real parts its easier at audio...)

: Apples and oranges. The phasing SSB exciter is using an audio
: *phase shift network*, the filter exciter is using a RF filter.

I think Zack was referring to the input audio filter.

: Now the AF phasing network may be considered a sort of filter,
: but that's not it's designed purpose, and for sure it's not a
: 3 kHz bandpass response. Instead it has to maintain a constant

: 90 degree phase shift across multiple octaves. That's tougher.

But the hard part is getting the ampltude and phase matching
to within a fraction of a dB or degree. As explained above, if you
do that, the overall amplitude and delay response versus frequency
will be quite good.

From: jkaidor@synoptics.com
Message-ID: <CnG5ux.4rF@synoptics.com>
Source record: 118171

The back-to-back approach is a good one; I've used it before. Of course, you also hang your filaments across the low voltage between the two transformers. For a QRP project, you can also hang a voltage doubler off the output of the second transformer.

Another way is to do away with the transformer altogether. This can be safe if you use a single wire to the AC plug. The other wire goes to the shack ground. That way, if you plug in the unit backwards, instead of having a hot chassis, you have no power at all.

The SB-33 transceiver used a variant of this technique where they had a separate, isolated B- bus inside the rig. This was bypassed to the chassis by several disk ceramic caps. There was also a neon bulb on the back of the radio hooked up between the B-/Neutral and chassis ground. If you had the rig plugged in backwards the lamp would light, assuming that you had a shack ground. Also, a ferocious hum would appear on your signal, and the chassis would be slightly hot for AC, corresponding to the leakage through the bypass caps.

I remember seeing an article once where somebody used a transformerless power supply to power a homebrew linear. I believe it was a voltage octupler. Performance was reported to be excellent, because of the low impedance of the AC source. :-)

> to these claims. Is it the tap point on a coil, a bias resistor,
> obviously the device, or is it some arcane combination.

I'm no expert, but can think of a few things that will effect noise figure.

1) Device itself. Gate length is especially importent. Smaller the better.
2) Temperature, especially if its a HEMT. High electron mobility is helpful. The HEMT achieve this, but needs a low temp (liquid nitrogen 77K) to work well.
2) Drain (or collector)) current of device.
3) Mathing of the source (usually 50 Ohm) to the device. You normally need a mis-match, ie dont match for maximum power transfer. Data sheet give you more info. Clearly, changing coil tap positions will then alter noise figure.

Whilst expensive CAD packages are useful, few amateurs have access to them. If not, we can play around, and see what is best.

davek

PS. Whilse not a calibrated instrument, there is a design in one of the RSGB's handbooks for a piece of test equipment for tuning equipment for minimum noise figure. It basically uses a zener diode to generate noise. The source is switched on and off rapidly. The audio output of the receiver is fed into the instrument, which determines the ratio of audio output with the noise source on, to when it is off. You adjust the pre-amp, to maximise the ratio. I built one and it works well.

733. Re: How phasing SSB Exciters Work (Was: RF and AF speech processors)

Newsgroup: rec.radio.amateur.homebrew

Phasing type SSB exciters produce a higher fidelity output
than filter type exciters *using filters of the type typically
found in ham equipment*. If you get high quality filters like
the Lumda FDM telecom filters, you get do just as well with
a filter type exciter. These filters will run you about $125 each.

In any event, if the receiver is a transceiver, and it uses
the same filter for receive and transmit, then all the nasty
ripples you avoided with a phasing type transmitter will
be reintroduced at the receiver. So you really need a phasing
transmitter and phasing receiver to get "hi-fi" audio. Or
use Lumda filters at both ends.

(Lumda is a small outfit that took over the FDM xtal filter
market when the big boys pulled out after T1 replaced FDM for
99% of the telecom market. FDM is still used for phone calls
to Alaska and Hawaii. It's SSB but doesn't sound like ham SSB.)

Mark Glusker (glusk@mechcad3.esd.sgi.com) wrote:
: A related question -

: If one has a transformer without any labeling,
: what is the best way to figure out how much
: current it can handle at its various voltages?

Two suggestions, both based on the idea that the heat rise
in the transformer determines the current handling capacity:

First, measure the resistance of the windings, including the
primary. The losses in a typical transformer divide between
core losses and copper losses, and a reasonable assumption if
you don't have more info is that the two will be equal in the
transformer operating under load. If the core losses are less,
you estimated conservatively, not a bad thing. You have to
get a feel for what a typical core size can handle in terms
of volt-amps; use this to estimate a max volt-amps for your
transformer. Use the winding resistances to allocate this
total among the windings. Note that some high-efficiency
core materials could again bias your answer to the conservative
side, but this, again, is probably not a bad thing. As a
check, you can add up all the copper losses as R*I^2 for each
winding, making sure you reflect all the secondary currents
back to the primary to find its loss. The power you come up
with should be reasonable for the transformer.

The second method involves actually measuring the transformer
heat rise. Copper has (about) a 0.4%/C temperature coefficient
of resistance, so by measuring the cold and hot resistances
of a winding, you can determine its temperature rise. The
idea is to operate the transformer under load for a long
enough time for it to heat up. You can use the first
method to allocate relative loads to the secondaries, and
run the transformer with these loads. I'll leave it up
to someone else to suggest max temp rise, but modern
insulations should be able to stand quite a bit. 100C
seems like it should be safe. Note that that's the _interior_
temperature, not the temperature you would measure at the
surface. Using this method, you can actually check if one
winding is getting hotter than another, and you can
rebalance the loads to equalize the temperatures.

Note that in both methods, judgement is required, and it's
safer to err on the conservative side. A transformer can
be designed to operate at very high temperatures, but if

you don't know that is was, you probably shouldn't push it.

Note also: these methods don't tell you that you are operating the primary at the design voltage or frequency. It helps a lot to know that it was designed to operate from your standard mains power, and to know which winding the primary is.

Oh, oh, here we go again. The Ramsey kit is fairly easy to build, and yes they sell a cabinet. They don't perform that well, and you need sophisticated equipment, at least a spectrum analyzer, to tune them up properly. (Maximum output and cleanest output aren't even in the same ballpark) It's not a horrible choice if you have access to the right equipment. But you'd certainly come out cheaper, and have a higher performance radio, if you convert ex-commercial surplus radios such as Motorola or GE to amateur service. There'll be tons of those in the upcoming Dayton fleamarket for $50 or less.

: 1) Device itself. Gate length is especially importent. Smaller the better.

Though at 144 and 222 MHz, large gate devices such as the MGF 1801 and MGF 2116 usually win noise figure contests. The explanation is that they have less diffusion noise. However, on 2 meters, most people can't take advantage of such a low noise figure (location is just too noisy). A 0.2 dB noise figure preamp is pretty helpful for calibrating the noise figure setups, given that the uncertainty is often a few tenths.

One application that could use lower noise figure preamps is satellite work at 435 MHz and higher. A lower system noise figure preamp means you can often achieve good results with smaller antennas (less expensive and easier to point). Thus, instead of a 3 or 4 foot dish for Oscar 13 mode S working marginally, a really good preamp and a 2 foot dish could give excellent results.

: 2) Temperature, especially if its a HEMT. High electron mobility is
: helpful. The HEMT achieve this, but needs a low temp

Alan Bloom (alanb@sr.hp.com) wrote:
(concerning the generation of quadrature phase audio signals)

: But the hard part is getting the ampltude and phase matching
: to within a fraction of a dB or degree. As explained above, if you
: do that, the overall amplitude and delay response versus frequency
: will be quite good.

So, just how good is a practical network?

In some recent ARRL pubs (e.g., ARRL Handbook, 1987, pg 18-9) there's
a "matrix" type of phase shift network that claims to be able to give
good performance with loose-tolerance parts. I put this network into
Spice last nite, and thought some might be interested in the
results. Below are four columns plus a frequency column. The
second column is phase of one output channel. The third is that
phase with a constant 235 degrees and a ramp at -.066 degrees/Hz taken out.
The fourth is the magnitude frequency response for that channel.
The fifth is the magnitude frequency response with an additional
5-pole Butterworth low-pass at 3kHz and 5-pole Butterworth high-pass
at 320Hz, to limit the audio passband to the 300Hz-3kHz voice band.

(I hope tabs in the table won't make it unreadable at too many sites.)

freq	phase error	mag	filtered mag
Hz	degrees	degrees	dB	dB
200	-193.5	54.6	2.2	-8.4
230	-203.8	46.4	1.9	-6.1
264	-214.0	38.4	1.6	-4.0
303	-224.4	30.6	1.3	-2.3
348	-234.9	23.1	1.0	-1.2
400	-245.6	15.8	0.7	-.5
459	-256.5	8.8	.5	-.1
527	-267.6	2.3	.3	0
606	-278.8	-3.8	.2	0
696	-290.2	-9.2	.1	0
800	-301.6	-13.8	0	0
919	-313.1	-17.4	0	-.1
1056	-324.5	-19.9	0	-.1
1213	-335.9	-20.9	0	0
1393	-347.1	-20.2	.1	0
1600	-358.4	-17.8	.2	0
1838	-369.5	-13.2	.4	0
2111	-380.4	-6.1	.6	-.1

2425 -391.1 3.9 .8 -.5
2786 -401.7 17.2 1.1 -1.2
3200 -411.8 34.3 1.3 -2.4
3676 -421.5 56.1 1.6 -4.1

Note: I didn't calc the phase error including the Butterworth filters, which are NOT linear phase, but better than the Chebyschev typically approximated in a crystal filter.

The exact meaning of the "phase error" column is certainly open to discussion, but to me it's obvious that it's a very low error, and quite smooth with frequency. And both the magnitude columns show extremely good flatness in the voice band: particularly the one including the out-of-band audio filters.

I didn't include columns about the phase and amplitude difference between the channels, but it's a very close match in both.

(I hope to follow this with another followup about actually achieving 90 degree phase differentials with a finite number of poles and zeros, but that will have to wait for now.)

Well at worst I've stirred up an interesting discussion. :-)

In article <CnG3Jt.Htw@srgenprp.sr.hp.com> alanb@sr.hp.com (Alan Bloom) writes:

>The audio phase shift network is the interesting (read difficult) part
>of the system. It must maintain a 90 degree phase difference and

> 360 deg / /
> I / /
> / / Q
> 180 deg / /
> / /
> / /
> 0 deg ___/_/
> | | | | |
> 300 600 1200 2400 4800 Hz
> Frequency
>

Now this chart illustrates the problem I've been talking about. As
we can see, the difference in delay with frequency is quite marked.
Sure the phase delay increases *smoothly* with frequency delta, but
the magnitude of the error rapidly climbs with increasing frequency
delta. This is our old friend click-boom. From 600 Hz to 2400 Hz delay
decreases by almost 20%, or about 0.2 ms. That much delay difference
is clearly audible.

If we look at Tom Bruhns' chart for a more complex matrix network:

phase filtered
>freq phase error mag mag
>Hz degrees degrees dB dB
>200 -193.5 54.6 2.2 -8.4

>400 -245.6 15.8 0.7 -.5
>527 -267.6 2.3 .3 0
>606 -278.8 -3.8 .2 0
>696 -290.2 -9.2 .1 0
>800 -301.6 -13.8 0 0
>1056 -324.5 -19.9 0 -.1
>1213 -335.9 -20.9 0 0
>1600 -358.4 -17.8 .2 0
>2111 -380.4 -6.1 .6 -.1
>2425 -391.1 3.9 .8 -.5
>2786 -401.7 17.2 1.1 -1.2
>3676 -421.5 56.1 1.6 -4.1

Now this is much better. The ends are horrible of course, but in the region 600-2400 Hz there is only a delay delta of 0.014 ms. That's hardly audible at all to someone with *good* ears. I'd note that this matrix phase shift network is considerably more complex than typical networks found in older phasing type equipment. And as Richard Karlquist noted, that's all for naught anyway unless the IF filtering of the receiver has correspondingly flat phase delay. Good RF filters can be as flat away from their edges as the matrix above, and RF filters work both ways.

<much deleted>

So, the audio phase shift is the only 'interesting' part...
How, pray tell, can one having only the usual ham test gear (scope,
probably, dmm, maybe power supply) make the RF phase shift be 90
degrees and the same amplitude at, say 12MHz?
My dual-trace scope is not perfectly calibrated, so that's
out. Generating 48MHz and using flip-flops to get 12MHz in quadrature
doesn't work well in reality (theory is great, but unless your 48MHz
signal is *exactly* 50% duty cycle it has a *strong*component at just
under half of 48MHz, usually near 22MHz. Flip-flops, like all
non-linear devices, are very good as mixers, and the 22MHz mixes with
the 12MHz to make some *interesting* spurs. Filtering out these spurs
usually trashes the 90 degree and equal amplitude you got in the first
place, leaving you back at square one.)(yes, i do know about this.
i've tried it. repeatedly. i KNOW phasing sounds better, and i

WANTED it to work *sigh*). Generate it in quadrature with a dual DDS
and two DACs? Then you must filter the DACs outputs through two
different filters, introducing slightly different phase and amplitude
errors.
I wanted it to work. Really. I've listened to DC receivers
and to crystal filtered super-hets and the difference is amazing.
However, I also want to be able to build a receiver and actually *use*
it, not spend eternity designing the 'perfect' one.
One other interesting thing re: phasing vs filtering: you'll
need *some* additional filtering to do a transmitter anyway (for SSB
at least). This filter will cost you $$, and if you already have to
spend the $$ why not use it for the receiver too? That rather neatly
explains why darned few commercial ham rigs use phasing any more.

: loop to recover clock, and sample the slicer waveform at bit centers to
: data detect.

Wrong.

Costas and squaring loops are used for CARRIER recovery, not clock
recovery. Discriminators have been used to recover PSK where optimum
performance is not required, but synchronus detection is far better.

The classical approach is to use a Costas loop in a quadrature mixing
arrangement so as to recover the I and Q quadrature baseband signals.
Clock recovery is a second phase locked loop that utilizes the I,Q, or
both signals as its input. It is the I and Q waveforms that are sliced
and sampled by the clock recovery. The two resulting bitstreams then
typically go into a decoder and then a bit stream re-combiner.

If the data carrier is only BPSK instead of QPSK, the output of the
Q channel will be zero. Any coding that is employed will only need to
operate on this one channel and of course a bit-stream re-combiner will
not be necessary.

QPSK is simply two BPSK signals that are combined in quadrature.

746. How To Receive Fm Subcarrier Signals

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-03-31 04:52:00 UTC
From: Timothy.Cadigan@f239.n109.z1.fidonet.org
Message-ID: <f9d_9403310042@blkcat.fidonet.org>
Source record: 118185

Kevin, a quick and dirty way to hear the subcarrier is to take the
audio out of the phone jack, and run it into the ant. of a general
coverage reciever. I use my IC-725. Switch to FM mode and tune
down between 50 and 80 khz. Connect the audio out ground to
ant terminal ground and run the audio "hot" through a small cap.
You may have to play with the value of the cap for best audio.
Tune the FM reciever around while twirling the gen coverage knob.
You should hear some subcarrier signals, especially if you are
in a big city. A better way would be to tap the the signal
out further up the chain from the audio jack. Use a small coax to
make the run from the FM receiver to the gen coverage receiver.
Best of luck!

: nothing detailed about how to do it.

A cheap and dirty way to do this is with a delay line IFM
(Instantaneous Frequency Measurement). The input is split,
one path is delayed (delay = desired pulse width = not much),
the two are fed into a quadrature phase comparator (which
is just an IQ detector where one of the signals is used
for the LO). Then filter the crap out of the output and AC
couple it.
It's not pretty, but its cheap and small.

I am frequantly faced with this problem. After I make my best quess using methods similar to those that other posters suggested, I hedge my bets a little. The fist time I apply power to what I think is the primary, I supply it from a variable auto-transformer and slowly increase the voltage while monitoring the other windings with a voltmeter (set to the highest range!). In case I make a mistake despite this caution, I hook a 50 to 100 Watt light bulb in SERIES with the primary. Not accross it, but in series to limit the current. An unloaded transformer should not draw enough current to light the bulb. If it starts glowing brightly, find out what's wrong.

In my opinion, no one who does much home brew should be without a variable auto-transformer and a light bulb hooked up to jumper clips. They are useful in many circuits when caution is called for. When I used to do TV service, for instance, if I got a set in with a shorted horizontal output, and no other problem apparent after a normal check, I would temporarily replace the fuse with a 100 W light bulb. It saved the new transistor on several occasions. 12 V bulbs of various sizes are useful for lower voltage circuits. Get the larger sizes as automotive parts.

Amen! I strongly agree with all that Jim wrote in that followup. If you can't afford a variable auto-transformer yet, at very least use the light bulbs. Note that light bulbs have higher resistance when hot than when cold, and so tend to act as "constant current" devices; different power bulbs can be used for different expected currents.

Also, if you can get to the actual winding wire on a transformer, a pretty safe rule of thumb is "700 circular mils per amp." Some old transformers were done at 1000 or so, but I think all modern ones would be quite safe, especially in benign ham applications (not out in boiling sun) at 700. Wire tables should have the circular mils listed vs gauge, but it's just the diameter of the copper in mils, squared.

After you've determined the safe RMS current load for all your windings, be sure that you take into account that the average current delivered by a capacitor-input-filter rectifier circuit is much less than the RMS current it puts through the transformer winding. A 2:1 ratio isn't uncommon. And a bridge rectifier makes more efficient use of a transformer than does a full wave center-tapped.

This implies you cover the carrier then recover the clock. On the
other hand there are remodulator schemes that recover the clock without
need for carrier recovery, then use the recovered clock to remodulate
the incoming data so as to recover the carrier. [i.e. it is possible
to recover just the clock (not the data) without first recovering the
carrier].

There are also differential self clocking schemes that don't require
any formal clock PLL.

You're right that the discriminator idea is a non starter for if you
want anything close to optimum performance. Among other things, the
DC drift is a nightmare. In general, Costas loops
work far better than squaring loops when properly designed. Unfortunately,
they are considerably harder to design properly compared to a frequency
doubler (= a full wave rectifier, which is hard to screw up).

>QPSK is simply two BPSK signals that are combined in quadrature.

A semantic nit here. Two BPSK signals in quadrature is described as
4QAM. It is only identical to QPSK in the absence of any data filtering
at the transmitter. Otherwise, the 4QAM signal will not have constant
envelope, but a true QPSK signal will have constant envelope.
You can make a similar argument that "BPSK" signals with data filtering
ahead of the modulator are really ASK signals because again the envelope

is not constant.

: we can see, the difference in delay with frequency is quite marked.
: Sure the phase delay increases *smoothly* with frequency delta, but
: the magnitude of the error rapidly climbs with increasing frequency
: delta. This is our old friend click-boom. ...

Other people besided Gary may be confused by this, so I'll post an
explanation.

The graph above plots phase, not delay. A constant delay results in
a constantly-rising phase plot. For example, a 1 millisecond delay
is 36 degrees at 100 Hz, 360 degrees at 1000 Hz, 3600 degrees at
10,000 Hz, etc.

Constant delay does not cause the "click-boom" that Gary mentioned. Think about it: You could record a voice on a tape recorder and play it back DAYS later without any "click boom." It's only when the delay is different at different frequencies (that is, the phase versus frequency plot is not a straight line) that there is a potential problem.

While the plot above looks like a straight line, it really isn't because of the logarithmic x-axis. However, as the chart that Tom Bruhns posted of a typical phase-shift network shows, it really isn't too bad. His chart shows that between 400 and 2786 Hz, the maximum phase error from a straight line varies smoothly between +17.2 to -20.9 degrees, which is far better than you would get with a typical transceiver-type crystal filter.

I expect most of the delay variation would come from the audio filter (that comes before the phase-shift network). Such a filter can be much flatter than a typical crystal filter for the three reasons I mentioned in a previous posting: (1) Doesn't need as sharp a cutoff as a receiver-type filter, (2) Can use a filter type with inherently flatter delay (non-Chebyshev), and (3) Pole Q and placement are much easier to control at audio frequencies than at RF.

Alan Bloom (alanb@sr.hp.com) wrote:
: In another thread, I claimed that phasing-type single-sideband generators
: sound better than filter-type generators because phasing exciters have
: flatter amplitude and delay response.

Yesterday, I posted results of a simulation of a quadrature audio network outlined in the ARRL Handbook. One thing to note is that the phase ramp is as Alan suggests in his posting. The "frequency" column is in 1/5 octave steps, and the delta phase between entries is practically the same across the band. So the phase looks like a straight line on a log-frequency scale.

But what if it was a design goal to come up with a quadrature phase network with flat frequency response and linear phase? Would that be possible? I think so, and I offer comments below in support of that idea. If I don't get to it, maybe someone else can check out the suggestion at the end to see if it really can work.

Soapbox: I'm treating this as a design problem, not something to wave my arms about. I start by summarizing some things that are likely to be relevant that could be tools to lead to a good solution. There is an assumption that flat response and linear phase will lead to something that people will think "sounds good." That may be wrong, but so far there seems to be good agreement about it. My purpose here is to simply explore ways to achieve this in a phasing system. This does NOT say that the same thing can't be done with filtering at carrier frequencies.

Observations:

0. The relative phase and amplitude response of a system can be completely determined by the positions of the poles and zeros representing the system; there is no need to commit to a particular physical implementation until the desired pole and zero positions are determined.

1. If a pole at -x+jy is balanced by a zero at +x+jy, the frequency response from that pair is exactly flat. The phase response, d(phi)/df, is exactly twice as much for such a pair as it is for the pole alone, at every frequency.

2. Techniques exist for putting poles at any interesting place on the left half of the s-plane, and for putting zeros at any interesting place on the s-plane. For example, for audio work, state-variable filter blocks can do this.

3. If one channel of a quadrature audio network has a phase ramp
vs frequency d(phi)/df = x, then the other channel must have
the same d(phi)/df over the band of interest to maintain a
constand phase difference between the channels. Since d(phi)/df
determines group delay, the two channels will have identical
group delays.

4. Linear phase is characterized by d(phi)/df invariant with frequency.

5. A strict delay has zero phase shift at zero frequency. Thus to
achieve quadrature phase, at least one channel will be characterized
by a phase shift in addition to any delay, even if d(phi)/df is
invariant over the band of interest.

6. None of the above precludes having a constant d(phi)/df in each
channel with a constant 90 degree phase difference between channels
and a flat frequency response in the band of interest. However, it
also doesn't tell you how to achieve this--it only provides some
hints.

7. A maximally-flat-delay (MFD) filter achieves a very constant d(phi)/df
over its passband.

8. A MFD _lowpass_ filter has nearly constant d(phi)/df through zero
frequency, and zero phase shift at zero frequency. It represents a
simple delay.

9. A MFD _bandpass_ filter has nearly constant d(phi)/df over its
passband, but not outside. The result can be a phase shift relative
to a MFD lowpass in the shared passband. THIS IS A KEY TO A POSSIBLE
ANSWER TO THE ORIGINAL QUESTION!

10. It _should_ be possible to find a pair of MFD filters with overlapped
passbands (either two bandpass filters or a lowpass and a bandpass)
which have equal d(phi)/df and a 90 (or 45--see paragraph 11) degree
phase difference between the channels in the shared passband.
Actually finding such a pair is the exercise remaining to be done!
Any volunteers?

11. MFD filters are notorious for non-flat amplitude response. This can
be taken care of by invoking paragraph 1: put a zero in for each pole,
which will double d(phi)/df and make the frequency response dead flat.
This is why we only need 45 degrees between the MFD filters used as
prototypes as suggested in paragraph 10.

12. Expect that it will take fairly high order filters to accomplish this
over the 300Hz-3kHz band. Tenth order wouldn't surprise me, to get
0.1 degree matching. The amplitude matching will depend only on
how accurately the implementation can place the poles and zeros at
the desired positions.

As a simple feasibility check, I asked a curvefitter to fit to a couple
linear phase ramps with constant amplitude, offset by 90 degrees, in the
range from 300Hz to 3.5kHz, and it didn't have any trouble getting

within a tenth dB and under a degree, with about 14 poles and 14 zeros
for each. None of the poles was particularly high Q: max about 8.

Yes Virginia,

There is a Transverter Jack on the TS-430. It is an 8-pin DIN connector
used to interface a VHF or UHF transverter. (I am quoting the manual. I
never used it....)

757. Looking for FTP site

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-01 02:25:44 UTC
From: Bob Lombardi <boblombardi@delphi.com>
Message-ID: <hu3vxvY.boblombardi@delphi.com>
Source record: 118197

I have a program that I would like to find an ftp site for.

For the last several years, I have been working on and using
a filter synthesis program called FilDes, or FDS. I'd like to
get it into the hands of hams or others who might find it useful.
FilDes designs lumped element filters: Butterworth and Chebychev
lowpass, highpass, bandpass, bandreject and coupled resonator
(narrow bandpass) filter characteristics are available. Chebychev
filters can be synthesized in any degree of ripple from 0.001 to
3.000 dB, and specified by either ripple or 3 dB bandwidth. In
addition, elliptic LP and HP filters are available.

In 1990, FilDes was a "selected entry" in RF Design magazine's
SW contest. Since then, I've made a lot of improvements to it,
and improved its usefulness. The version in RF design was 1.0,
it's currently at rev. 1.24. FilDes has been used professionally
to design many filters. Some are already in use in commercial
equipment, and others are scheduled for launch into space within
the next few years.

FilDes is the direct descendant of a program I wrote that designed
only the narrowband coupled resonator filters in only a few choices
of transfer characteristics. This program was written on the C64
and an article with it was the cover story in Ham Radio for March,
1986. FilDes was written in Turbo Pascal and runs on pretty much
any PC clone. A math coprocessor will be used if present, and speeds
up the elliptic filter section. A color monitor is not strictly
required, but I really don't know if all I/O screens are legible
on monochrome.

Because I pay per minute for this connection, I'd like to put it
on an anonymous FTP site. I hope that the combination of the
online help and the doc file that comes with it can explain
everything a new user would need to know. Because Delphi's ftp
connection doesn't allow binary upload, I will need to uuencode it
and then transfer it to the site. The site manager will need to
uudecode it.

If you run an anonymous ftp site, let me know, and I'll ftp or
even mail it to you (since it will be a uuencoded .zip file).

73,
Bob

I really didn't know there WAS a difference between 4QAM and QPSK. EVERY BPSK or QPSK radio I have ever worked on has had data filtering ahead of the modulator. I have found true "constant envelope" PSK to be rather uncommon, although it is certainly desirable when you must use non-linear PAs. Offset QPSK is relatively common and the envelope is "sort of" constant.

Your point could be defended if one was to take the rigid stand that in PSK *ONLY* the phase should change, but the world does not seem to have taken that stance. Rather, the information is contained in the phase changes, and the path between states does not seem to enter into whether you should call it PSK or not. QPSK, under this less rigid definition, could also be called 4QAM. If knowledge of the phase is not enough to define the symbol, as in ANY non-circular constellation, than the convention is to call the modulation QAM.

You can NOT reall draw an equivilence between BPSK and ASK since a "1" and a "0" have the same amplitude -- a diode detector cannot tell the two apart. There is no quadrature component transmitted, so 2QAM would not be appropriate either :)

>An unloaded transformer should not draw enough current to light the bulb.
>If it starts glowing brightly, find out what's wrong.

An *excellent* tip. I do this myself. I've got a selection of bulbs,
from 220 volt rough duty models, to 110 volt ordinary incandescents,
to 12 volt automotive lamps, to little flashlight bulbs all mounted
on a load board. I can select the proper load for power supply testing,
current limiting, etc, in a matter of seconds. If I make a mistake,
all I'm out is a light bulb, not a zorched piece of expensive gear.

Source record: 118212

While this is fascinating, you are all going way over my head. (The exception is the discriminator suggestion -- I understood that.) Can anyone suggest a good book from which I could figure out how these demodulators work?

My particular interest is doing the BPSK demodulation in the 70 cm or 33 cm bands, for use in a direct-sequence spread spectrum receiver. No, I'm not planning to build the thing any time soon. It's just a paper design so I can get a grasp on how these things work.

Hello,

I would like to play around with what I would call an intelligent house,
(so I can concentrate on doing QSOs!!). By this I mean that a computer
would turn on fans or heaters depending on the theperature or humidity.
I am more a software person and can take care of that part but would like
to buy the probes or sensors that would tell the computer what the persent
temperature or humidity is.

Would anyone know where I could get stuff like that from, an address
or phone number would be greatly appreciated. Thanks!

73,
Michel VE9MDL

PS: Also looking for solar cells, would like to run my radios from
a battery "charged" by the sun.

The ARRL handbook has a nomograph that you can use to estimate the
total power available from a transformer.. It is based on the area of
the core/windings and will give you a ball park figure to work from.

I think it is in the section on power supplies...

769. Minisport Hacker #21

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-01 18:33:20 UTC
From: bmork@opus-ovh.spk.wa.us
Message-ID: <0D04Jc6w165w@opus-ovh.spk.wa.us>
Source record: 118205

MiniSport Laptop Hacker - Vol #21. April 1994
To discourage pecuniary interests, Copyright (c) 1994 Brian Mork

>>> ADMIN
The MLHacker series is formatted to print out on 8.5"x11" sheets manually fed into an Epson LQ-850. I print at 8 lpi, which gives 82 lines per page. My goal is to make each MLHacker one to two pages, to fit front and back on one page. Back issues are available via Internet e-mail and ftp archives and direct from my data line listed below. File download privilege is given on the first call. Use the F)ile option and L)og into the \public\computer directory. No cost 'cause I just like doing it. Do something you're interested in for free and pass it on!

The Air Force has me committed to some massive amounts of overseas flights during April and May. For this reason, I expect MLHacker will take a hiatus during that time.

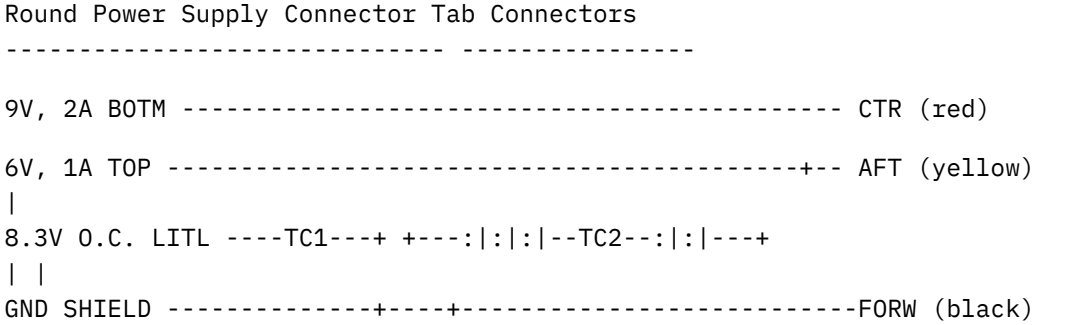
>>> AUTOMOBILE POWER SUPPLY
Something has been bothering me ever since issue #12 of MLHacker. I mentioned how you could tap into your car cigarette lighter, step the voltage down to 9 volts and use that to power your Minisport. So far, true. My bad recommendation was the placement of a noise-killing capacitor and inductor.

Yes, put a big inductor in series (old lamp ballast works fine) to kill ignition glitches. But don't put the capacitor on the car side of the inductor. Put it on the *computer* side of the inductor. The problem is this: When you switch off the computer, the magnetic field sustained by the inductor collapses, forcing continued current flow. But the computer is off! Being off is a high resistance. As the charge collects on this high resistance, the voltage peaks very high. To some extent, the internal Minisport battery, which is effectively in parallel across the power line, begins to conduct (i.e. charge up) as the voltage rises, so there is some limit on the voltage. But I was wrong to suggest putting the capacitor where the inductor could feed off from it. It's much better to put it on the computer side, where it will dampen the inbound current. An additional improvement would be to put a diode across the inductor (cathode, banded end toward the car). It will then short out the inductor spike upon power-down.

Some folks have indicated they run the Minisport straight from 12 volts. I'm not sure I'd recommend that, but I'd be interested in anybody's success doing this. Battery? Direct from car? One MLH reader is working to modify a drill battery pack to power his Minisport. I hope to talk him into writing up notes on the project.

>>> INSIDE THE BATTERY PACK
Jim sent me a dead battery pack to rip apart. Aha! The final link to the puzzle. MLH #12 discusses the wall adapter/battery pack connection. MLH #14 discusses the battery pack/computer connection. Issues #17 and #18 discuss the switching power supply board inside the Minisport. Finally, here's the stuff from inside the battery pack. In the process of documenting this, I discovered another error from issue #12--my description of the small pin on the 3-pin charging connector. I believe the information provided here to be the correct interpretation.

BATTERY PACK INTERNALS



There is also a tiny chip capacitor between the 9V supply rail and ground. A parallel surface mount spot (for a resistor?) is empty on the circuit board inside the one battery pack I've inspected.

The charger adapter has four connections: the shield, two similar pins, and a third pin smaller than the other two, thus the titles BOTM, TOP, and LITL. The tab connections on the bottom of the battery pack correspond to the three slide connectors visible inside the minisport when you remove the battery pack. The colors correspond to the wiring color visible inside the computer when the bottom is removed.

TC1 is a thermal cutoff unit, tightly mounted to the battery cell closest to ground. TC2 appears physically similar. While charging this battery pack, I monitored the voltages on the power supply connector. BOTM was 9.2V, TOP was 7.6V, and LITL was zero volts. I applied a heat gun onto TC1, and at 0:12 the voltage at LITL jumped up to 8.3 volts. At 0:40, TC1 closed and the voltage at LITL went back to 0 volts.

It seems clear that the design of this system is to overvoltage the batteries (7.2v onto a 5x1.2 => 6.0v battery pack) and when the batteries get warm, the thermal cutoff ungrounds a signal back to the charging unit. To confirm that the charger responds to the signal, I loaded the battery pack with a 20 ohm resistor and hooked up the charger, giving 7.2 volts across the resistor (about 350 mA drain, 2.5 watts). I would expect that if the charger shut off, the voltage would drop a little bit as the battery pack picked up the entire load and started discharging. Sure enough, after about 20 seconds of heating TC1, the voltage across the resistor dropped to 6.8 volts.

Heating TC2 has expected results. While charging, I measured 7.0 volts across an unloaded, charging battery. At 0:20 of heating, an audible

click occurred and the voltage dropped to 2.9 volts. I turned off the heat gun and at 1:14, I heard another click and the voltage comes back up. While *not* charging, the voltage goes from 6.5 to 0.0 with nearly identical timing. I think the 2.9 volts observed while charging was residual output from the charging unit.

>>> BAYCOM VS POOR MAN'S PACKET
Poor Man's Packet software works fine to receive packets on the Minisport using the hardware described back in MLHacker #9. It does not work on transmit. If you try to send a packet, the transmit tones just lock up at 1200 Hz or 2200 Hz. This was confirmed using another ham's (thanks Ron) PMP hardware rigged to run off COM1 (normal DB-9 out the back). PMP is written in C, including the AX.25 bit packing routines. I think these are just not fast enough when run on the 8 MHz Minisport.

Baycom uses a separately loaded driver to talk to the hardware. It's small and efficient, probably written in assembly. I got a copy of Baycom software and using Ron's Baycom hardware, which was rigged to operate on a parallel port, everything worked fine.

Conclusion? The Minisport needs bit packing routines written in assembly. Baycom offers this; PMP does not. I thought the PMP hardware was designed to be bit compatible with Baycom (e.g. RTS does the PTT function, and so on). Apparently, this is not so. When I redirect the Baycom to COM2, it does not work with the PMP hardware I built and described in MLHacker #9.

I don't have the time right now to do an assembly rewrite of the PMP software, so I want to figure out how to use the Baycom software. Anybody out there more familiar with Baycom and what bit lines it uses for what? Eventually I'll poke around and find out what's going on, but maybe somebody could save me the trouble.

>>> FUTURE PROJECTS
I saved up money for several months and purchased a Fluke 97 digital storage scope / DMM "do everything" box. It's roll mode data monitor worked great for probing the battery pack. Expensive, but a *superior* bench top accessory. I'm interested in anybody using one of these. Mine has an optical data interface and that will, I'm sure, eventually be hooked to my Minisport.

I also picked up a 670 nm laser diode assembly, including a photodetector and stepper motor. The light beam comes up through the shaft of the stepper motor, allowing the outbound beam to be aimed onto one of eight mirrored segments, and reflected forward. Inbound light is collected by all eight segments simultaneously and focused onto the on-axis photodetector. I wonder if I can hook this up to the computer to do a laser light show. Or maybe a proof of concept optical radar. Hmm... :-)

770. QRP-linear for HW-7?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-01 19:05:30 UTC
From: MIKSUORA@SARA.CC.UTU.FI
Message-ID: <CnLH16.5oz@utu.fi>
Source record: 118206

HW-7 QRP-rig has output power of about 2...3 watts, depending
on the frequency band used. This is quite enough if one has a
proper antenna. Sometimes I do /P -operations and have to live
with a lousy longwire... A few more watts of power to compensate
my poor antenna would be great. Power comsumption will not be
a problem 'cause I can use car battery.

Has anyone built a small broadband amplifier to go with HW-7?
1..2 watts input and maybe about ten watts of output power. I
assume this could be a simple one or two transistor project. If
you have experience, simple plan, some "do and dont's"..let me know!

|>
|>

A couple of problems:

1. Aircraft frequencies are AM, which most FM receivers are designed to reject. You'd need to eliminate the IF limiting and change the characteristics of the detector in the receiver to accomodate this.

2. Broadcast FM channel bandwidth is large - around 150 kHz, with 200 kHz spacing between channel centers. Channel spacing on the aircraft band is 25 kHz, meaning that several adjacent aircraft channels would be received simultaneously. This may or may not be a problem in your particular area. Narrowing the bandwidth of the receiver is a non-trivial task.

It would probably be easier to modify an old public service band (146-174 MHz) receiver, since its bandwidth is narrower. Ramsey has a kit aviation radio that runs about 30 bucks, that would probably be much less difficult to deal with. Some available scanners pick up the AM aircraft band, but the cost considerably more.

Dan Kerl
dlkerl@ingr.com

PS - Ramsey's number is 716 924-4560. I have no connection to them.

776. Re: How To Receive Fm Subcarrier Signals

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-02 14:48:47 UTC
From: joe@netcom.com
Message-ID: <joeCnMztC.Kuy@netcom.com>
Source record: 118216

I recently ordered and received three SCA demodulator boards from SCS Radio Technology after noticing an advertisement in Radio News. Bruce Elving's SCA design uses a CA3089 IF/detector chip and a PLL (I designed his XR2211 PLL SCA demodulator) SCA. Bruce also sells FM receivers modified with the boards.

What was interesting about the SCS SCA board design, while it uses a CA3089E IF chip also, a multipole filter in front of the 3089 decreases main channel crosstalk interference (by 60 dB). David's board is of excellent construction, with no jumpers and small size to be inserted in an FM receiver's FM detector stage (before deemphasis attenuates the SCA signals).

Anyway, three pretuned boards are available from SCS, 57Khz, 67Khz, and 92Khz - $20.00 each, $60 plus $6.00 P&H for all three. I am satisified with the design and construction of each board. One area of modification I would make is to monitor the SCA signal's multipath and level with an x-y monitor. Use pin 13 of the 3089 chip for a signal level (scope y) output and pin 7 for the y axis output. Of course levels must be set to set vertical and horizontal traces. A flat vertical line, max amplitude, is the ideal signal for tuning. A "wavy" line illustrates multipath. This is a great tool for tuning FM signals...

SCS's Address and Phone Number:

SCS Radio Technology
5742 Fairoak
Springfield, MO, 65810

Phone:

417-881-8401

He (Dave Jackway) takes checks only at present. While his focus is large-volume customers, he will sell to the small customer...

(I have no affilication with SCS, only as a satisfied customer)

Folks,

I thought I'd post a little information on my experencies with the RAMSEY SCA decoder kit.

The RAMSEY SCA decoder attaches to an FM radio just after the detector and is supposed to allow you to listen to subcarrier transmissions such as Musak ("elevator music") that are broadcast with commercial FM stations.

The short summary is that my kit did not work after it was assembled. I believe that this is due to a design defect in the product. While the Ramsey documentation states that the kit can tune the full SCA frequency range, the kit has a passive input filter that is a band pass only at a particular frequency. You can tweek the tune knob all you want and that input filter will only allow a narrow band of frequencies into the SCA decoder.

The design defect is the input filter is miss tuned. A little analysis with ACS (Al's Circuit Simulator) shows that the peak response of the filter is at 53.5 Khz. That's too bad since the SCA signal is at 67 Khz. The response of the filter is down by about 40 dB at 67 KHz.

A friend of mine called Ramsey and they suggested changing three components:

C4 should be 150 pf (was 100)
C5 should be 0.003 uf (was 0.005)
C6 should be 0.003 uf (was 0.005)

This moved the peak response much closer to 67 Khz. Now my SCA can hear stations that transmit their SCA subcarrier at that frequency.

For Dallas area listners I hear audio stations on the following FM frequencies:

90.1 -- Seems to be Reading for the Blind. Someone reads local newspapers and portions seem to contain material from non-local sources. A bit

dry but I got to hear Dave Barry's column last Sunday. Might be
nice for drive time listening.

94.1 -- Elevator Music
105.3 -- Elevator Music

I also hear lots of digital signals on the SCA channel of other stations:

97.1, 99.5, 100.3, 103.7, 107.5

Does anyone know what these are? I've heard of the POCSAG and Golay pager
formats, might these stations be using these type of transmissions? Does
anyone have any pointers to the description of these formats?

Can someone tell me the standard subcarrier frequecies (besides 67 KHz) ?

-- Mike

PS. I used a PRO-2005 as my FM detector.

If anyone is interested, here are the plots of the input filter's response
(before and after being modified):

Glad you finally got it to work Mike. The B Subcarriers are at 92 MHZ. You
may hear much the same things as you hear at 67 MHZ. You should find some
Ethnic programming as well. Can't say about the data stations but there are
quite a few of them here in the Bay Area as well. Your Reading Service for the
Blind probably broadcasts live during the day and perhaps they go to the
satelite to receive the Intouch Network from New York at night. Listen for the
id's.

djc@terapin.com Out!

I would like to hear from Mike if the quality of the decoded sound was
acceptable after the mods were made. I ran the Ramsey ciruit thru P-Spice
and got the same results 40Db down at 67Khz and a bandpass to boot. I
wanted to hear some siganls in Dallas at 92Khz so I redesigned the BP filter
to pass 92Khz but the quality was BAD. I have an old SWTP SCA decoder from

the 70's using the 565 as well and it sounds better.

My question is the circuit did NOT work as put out and you have to change components to do so so why is RAMSEY putting out a BAD board and selling it for $25 in kit form. I finally went out and bought an assembled SCA from SCS radio for $20 ASSEMBLED 5 bucks less and no assembly and the sound quality is good!! See review below for details:

From: joe@netcom.com (Joseph Jesson)

I recently ordered and received three SCA demodulator boards from SCS Radio Technology after noticing an advertisement in Radio News. Bruce Elving's SCA design uses a CA3089 IF/detector chip and a PLL (I designed his XR2211 PLL SCA demodulator) SCA. Bruce also sells FM receivers modified with the boards.

What was interesting about the SCS SCA board design, while it uses a CA3089E IF chip also, a multipole filter in front of the 3089 decreases main channel crosstalk interference (by 60 dB). David's board is of excellent construction, with no jumpers and small size to be inserted in an FM receiver's FM detector stage (before deemphasis attenuates the SCA signals).

Anyway, three pretuned boards are available from SCS, 57Khz, 67Khz, and 92Khz - $20.00 each. I am satisified with the design and construction of each board. One area of modification I would make is to monitor the SCA signal's multipath and level with an x-y monitor. Use pin 13 of the 3089 chip for a signal level (scope y) output and pin 7 for the y axis output. Of course levels must be set to set vertical and horizontal traces. A flat vertical line, max amplitude, is the ideal signal for tuning. A "wavy" line illustrates multipath. This is a great tool for tuning FM signals...

SCS's Address and Phone Number:

SCS Radio Technology
5742 Fairoak

There's all sorts of digital information coming back on SCA channels. We
use our SCA for remote transmitter metering; it's Bell 103 300 baud between
a pair of computerized boxes.

There's SCA paging, there's the stock data service someone mentioned,
and all sorts of other stuff.

Ah..OK..good! Does an oscilloscope work as well as a real
x-y monitor? Its would be interesting to feed the multipath
axis signal to a vco and have a tone that dances to the
tune of the MP! :)

Im on netcom also as is obvious, and if you ever have the
time and that sort of forum would be more appropriate
than mail, im open to chat mode. You talk ill listen!
It is really nice to find another enthusiast of such
a specialized facet of radio and measurment.

Mike

Spring has sprung .. so it's time to start again

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS

FLEA all SUMMER at MIT
April 17th, 1994
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >1000 cars!

Buyers admission is $2 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

!! RAIN or SHINE !! Have no fear of rain, a covered
tailgate area is available for all sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)

>not be appropriate either :)
>--
>~~ dmiller@crl.com ~~~~~~

The difference is in the transitions. With BPSK, the envelope remains constant
and the phase rotates from 0 to 180 degrees. With ASK, the amplitude ramps
down to zero while at 0 degrees phase, then the amplitude ramps back up to
full amplitude while at 180 degrees. A diode detector with a Nyquist pulse
shaping network in front of it can definitely tell the difference. Only
the mode the filter was designed for will result in zero intersymbol
interference.

I think I have spend enough time researching this topic that I
can state with 99% certainty that there is no single book or paper that
describes exactly how to build a well designed BPSK demod, let alone
a QPSK demod.

Communications theory books (see Feher's books) show general block
diagrams of such things but leave out the critical practical
considerations. You have to figure those out on your own.
John Bingham's book on modem design goes into a little bit more detail
than most books, but it's no cookbook. The few hobbyist magazine BPSK designs
I have seen were very poor, although they will work after a fashion
if you fool with them enough.

>Other people besided Gary may be confused by this, so I'll post an
>explanation.

I'm not confused. I calculated the delays based on the graph you posted.
Delay equals the reciprocal of frequency times the total phase delay in
degrees divided by 360.

>The graph above plots phase, not delay. A constant delay results in
>a constantly-rising phase plot. For example, a 1 millisecond delay
>is 36 degrees at 100 Hz, 360 degrees at 1000 Hz, 3600 degrees at
>10,000 Hz, etc.

Yeah, but that isn't what your graph showed.

>While the plot above looks like a straight line, it really isn't because
>of the logarithmic x-axis.

Bingo! I check plotted it on semi-log paper then replotted on a linear
graph from which I calculated my differential delay numbers.

>However, as the chart that Tom Bruhns posted of
>a typical phase-shift network shows, it really isn't too bad. His chart
>shows that between 400 and 2786 Hz, the maximum phase error from a straight
>line varies smoothly between +17.2 to -20.9 degrees, which is far better
>than you would get with a typical transceiver-type crystal filter.

As I commented, his table looked much better than your graph, and I
calculated differential delays based on it too that were nearly 10
times smaller. It's just that I've seen phase plots for crystal and
mechanical filters which, *away from the edges*, where Tom's table
looked bad too, looked at least as good as Tom's phase shifter. And
note also that the network Tom modelled is not "typical", it is
considerably more complex than the traditional Dome based networks.
They tend to really suck in the differential delay department because
they're based on the same simple semi-log response as your graph. I
don't think he included an AF pre-filter in the table either.

I'll readily agree that the receiver type filters used in many ham rigs for SSB transmit signal generation, suck wind. But that's a different issue. Good filter designs are available, as witness filters we use for VSB video, and in certain telco FDM equipment that have a maximally flat phase response in the passband. We simply can't tolerate differential delay in video systems, yet we use filters instead of phasing to generate VSB signals. It's not a matter of economy, it's what works best.

Once again: it is NOT necessary for PSK to have a constant envelope.
If you disagree with this, go talk to one of your HP friends that are
working on the test equipment for North American digital cellular.
NADC is Pi/4 DQPSK and it does NOT have a constant envelope. Folks
have, and continue to ship what they call BPSK systems that fall
under your definition of ASK. To be consistant with your stand that
ONLY the phase changes in PSK, one would conclude that only the
amplitude changes in ASK, right? A phase change at the zero crossings
would not be allowed. It has always been my impression that ASK
was like sending data into an AM modulator -- complete with the
offset so that over 100% modulation was avoided. It should be
possible to get NRZ data directly from an envelope detector without
playing transition games.

Vendors such as Alpha Industries produce "Bi-Phase modulators" as
standard products for implementation in BPSK modulators. These products
have NO Q CHANNEL INPUT, so it would be impossible to generate a
constant envelope signal with them.

This "symantic nit" has turned into a rather lively discussion, it
would appear. I have checked the books at my disposal and can't
really find any that have drawn the lines between modulation formats
in the manner you describe. What sources have led you to these
conclusions? I would like to check into them.

That depends on the details of the supply. You might need to add some
extra supply filtering to get rid of a ~15 kHz switching whine.

An issue that should be of more concern is the voltage and current
ratings. A 200 Watt supply may not be able to supply all of that power
at 12V. A typical PClone supply can put out 35 amps or so at 5V,
perhaps 1.2 A at +12V and 1A at -12V, and a couple hundred milliamps at
-5V. This would be a poor match for a linear amplifier that wants 20
amps or more at 12V. If your supply is something weird that puts out
gobs of power at 12V, perhaps it is a good match. That is unlikely.

A computer supply can reasonable for other purposes. QRP rigs can run
off the 12V 1A output of a PClone power supply. Put an appropriately
sized resistor across the +5V line or else the supply might not be loaded
enough for good regulation.

We are trying to make a regulated power supply (suitable for Tx) out of a computer power supply. It is made by RW, a German manufacturer, called a PC40 power supply, that will take 110-240 volts, rated at 220 Watts (Part # 380708-02)

Our question is: Is the DC ouput sufficiently regulated to provide clean RF output out of a radio? Also, can one bank two of these power supplies in parallel and use the combined output (400 W) to drive a linear amplifier?

Tnx in advance

I think other posters have pointed out that this will NOT be a simple mod.
There are many cost-effective solutions to listening to the aircraft band
if that is the goal here. Check your local Radio Shack catalog.

Why? If it's an analog FM radio, couldn't you put an inductor or
capacitor in series with the tuning system to change the frequency, or
am I way off?

As I said, this is a semantic discussion. I don't agree with their
terminology, that's all.

>have, and continue to ship what they call BPSK systems that fall
>under your definition of ASK. To be consistant with your stand that
>ONLY the phase changes in PSK, one would conclude that only the
>amplitude changes in ASK, right? A phase change at the zero crossings
>would not be allowed. It has always been my impression that ASK

I am allowing "negative" amplitudes, so 180 degree phase shifts
(and only 180 degree phase shifts) are allowed in my definition of
ASK. Again, my definition.

>was like sending data into an AM modulator -- complete with the
>offset so that over 100% modulation was avoided. It should be
>possible to get NRZ data directly from an envelope detector without
>playing transition games.

The envelope detector cannot distinguish negative from positive
polarity so it doesn't work here.

>Vendors such as Alpha Industries produce "Bi-Phase modulators" as
>standard products for implementation in BPSK modulators. These products
>have NO Q CHANNEL INPUT, so it would be impossible to generate a
>constant envelope signal with them.

A true phase modulator should have only one input, "phase".
What I don't know about that specific one is if the phase port is
linear or digital. Modulators with I and Q inputs are for QAM.

To produce true BPSK, as I define it, take your NRZ data, run it
through a finite bandwidth pulse shaping filter, and then run it
into a linear, *analog* phase modulator (with no ideal switches).

To produce true ASK, as I define it, take your NRZ data, run it
through a finite bandwidth pulse shaping filter, and then run it
into a linear, *analog* bipolar amplitude modulator (a double balanced
mixer for example). If you don't like the bipolar aspect, bias
the data so it is unipolar.

As the bandwidth goes to infinity, the systems become more and
more alike.

If you don't watch what you're doing, you can easily get a combination of
the two with neither constant envelope nor constant (absolute value of)
phase. For example, following a BPSK modulator with a bandpass filter
produces AM via PM/AM conversion. Moral, do all filtering at baseband.
(That comment ought to produce so controversy!).

>This "symantic nit" has turned into a rather lively discussion, it
>would appear. I have checked the books at my disposal and can't
>really find any that have drawn the lines between modulation formats
>in the manner you describe. What sources have led you to these
>conclusions? I would like to check into them.

Essentially, these are my own ideas; you won't find any real discussion
of this in books, as far as I know. You'll just have to keep reading
Usenet to keep up :-) I have read every book I could
get my hands on about this subject, and they all gloss over the
details of implementation. As I said in another posting, try Feher's
books and John Bingham's book on modem design for starters.
(Ever notice how you never see a *schematic* in those communications
theory books, only block diagrams.)

>receiver isn't expensive.

I've retuned a cheap AM-FM portable to the aircraft band. It
sortof works, the sounds is low but audible, the wide bandwidth
brings in lots of noise and the tuning is picky (but the wide
bandwidth helps with the tuning).

Apparently the cheap FM detector does respond to AM.

I retuned the front end -- mainly changed the RF OSC coil to have
fewer turns. I think it tunes from the high end of the FM
broadcast band to somewhere slightly above the 2 meter band. I
also twisted the adjustments in the IF cans for peak output.
Probably narrowed the IF a bit (but not anywhere near enough).

PS: Very few 2 meter stations are actually audible.

I dont know what frequencies you're dealing with but below
1 GHz PIN diode switches do indeed generate intermod spurs.
I'm working from memory here, but as I recall, a typical
switch has a 3rd order 2 tone intercept point of about +40 dBm.
Above 1 GHz the intercept goes up so much it can be ignored.

The most robust easily duplicated design currently in print is the
Suffolk design in the RSGB book _The VHF/UHF Dx Book_. Chapter 8
includes a good discussion of why certain tradeoffs are made in
transverter design.

I found that cheap 1N4148 switching diodes can deliver adequate 3rd order
IMD performance at 2 meters--I measured an input intercept in excess of
+56 dBm. Loss wasn't a factor in the application, but its probably
a dB or two. It was biased with about 10 volts and 520 ohms of series
resistance. However, I didn't measure the 2nd order intercept point, which
might be more of a factor on HF receiver than a microwave IF radio.

I believe DownEast Microwave now offers a 2m transverter.. in fact, two
of them... one intended as an intermediate IF between an HF rig and a
no-tune microwave transverter and the other a higher power 2m "final"/
"frontend".

Unfortunately, I don't have DEM's number handy... but I'm sure you can find
their ad in 73, QST or someone else will surely post it here.

What I'd like to know-- is if the mentioned HR-2600 can be modified for
26 to 30 MHz coverage.. or is it likely to be potted with goo that prevents
you from getting to the appropriate jumpers, diodes or whatever. Very early
models were modifiable I understand... but recent ones were supposedly
potted. I've never seen one myself...

Gary Coffman (gary@ke4zv.atl.ga.us) wrote:

: Now this is much better. The ends are horrible of course, but in the
: region 600-2400 Hz there is only a delay delta of 0.014 ms. That's
: hardly audible at all to someone with *good* ears.

For some points in my table, I get the following approximate group
delays:

Freq, Hz Group Delay, ms
200 1.09
400 0.57
800 0.31
1600 0.15
3200 0.07

Dunno how Gary got 14 microseconds; you'd have to have better-than-
golden ears to hear that, from reports I've seen. Anyway, the numbers
in the table above are from

group-delay (seconds) = d(phase [radians])/d(frequecy [radians/sec])

As expected, they go essentially inversely with frequency.

: I'd note that this
: matrix phase shift network is considerably more complex than typical
: networks found in older phasing type equipment. And as Richard Karlquist

I recall having the values used in the B&W phase shift network around
somewhere, but couldn't find them. I wanted to put that into Spice
originally, cuz it would have been a lot simpler than that "matrix"
network. Can someone supply the values? I'd be happy to run them
for comparison.

Roger Traylor (rlt@ssd.intel.com) wrote:

: My question is: if PIN diodes are used to switch between different sets
: of bandpass filters will they cause increased IMD at typical (not
: pathological) signal levels?

It depends on the PIN diode. The longer the carrier lifetime, the
more it acts like a resistor and the less like a diode. PIN diodes
designed for microwave applications often have short carrier lifetimes
(to allow fast switching), so they cause lots of distortion at
lower frequencies.

Diode detectors will fry at +30 they are only good to +20. if you
use a 10dB pad infront then you meter needs to read down to -40.
this is not easy. you will need a chopper stablized front end
on your system. The biggest problem is thermal drift due to solder
joints (yes, solder joints!). I built the Wavetek 8542 power meter
and know all the tricks. you will also have problems with linearity
the diodes are only linear below -20 dBm and about that you need
to correct for them. detector design below 2GHz is easy and gets
very hard above that. If you are really set on this tell me the
details of what you are trying to do.

Another interesting case is to start with a conventional elliptic function
bandpass response, then proceed to the two networks with flat group delay
and 90 degree phase difference, keeping the nice elliptic magnitude response.
The finite jw-axis zeros may well wreak havoc -- with the number of poles
and zeros (for the same overall tolerances on amplitude and phase errors as
you have above) increasing significantly.

Is it practical to do computer-controlled plotting of etch resist directly on a PC board? I have a Houston Instruments flat-bed plotter that might prove useful for this. Three problems I see: (1) getting a pen with decent etch-resist ink that will fit the plotter, (2) finding a PC board CAD program that can talk to this old thing, and (3) making sure the plotter doesn't move too fast for good distribution of the ink.

Surely this has been tried already. Is it practical?

>Surely this has been tried already. Is it practical?

I have tried a number of methods to make pc boards. I now use resist
ink on copper drawn with a plotter. I use a HP9872 bed plotter.
I have heard of people using the smaller HP moving paper plotters
with some success.

I have been experimenting with using a steel tip pen on pc board
and have had quite good results. I have also tried fiber tip pens.
These are Staedler 31HP03K-2 pens for HP plotters. These work fine
as far as the resist characteristic goes. They are not so good on
line width. They take about a half inch to start drawing properly,
this with only 30 seconds of uncapped time before plotting.

The ink that I use in my steel pens is Staedtler 748 PLP red.
Before you run out and order it, it has been discontinued. Not
that they don't make it anymore, they don't import it anymore.
Their technical person told me that EPA labeling rules dictated
a warning label and they only sold $5000 worth of the stuff a year
so they stopped shipping it over. It is the ink used in the
31HP03K-2 pens.

I use a Staedtler 757-PL2-CS pen tip. This is a .25 mm, cross
groved, tungsten carbide tip pen. It produces consistant width
lines that have a consistent coating of ink. I also tried a
ordinary steel tip disposable pen. These come with the pen
tip not inserted into the ink cartridge. I punched the membrane
out and dumped the original ink out and refilled it with the
ink mentioned above. This worked just as good as the tungsten
pen tip and only cost $10 for the pen verses $50 for the tungsten
tip pen and adapter. The drawback is that after the ink runs out
of the steel pen you cannot refill it. The tungsten pen is refillable
and disassembleable for cleaning. You must slow the plotter
drawing speed. I use 1 CM per second, the slowest. The ink
cannot flow fast enough to keep up with the normal speed. The
speed is set whit a command to the plotter.

I have a brochure from General Consulting that sells
a system for direct plotting on copper. They plot on very thin
single side copper laminate and then later glue the thin laminate
to a thicker fiberglass substrate to get the final double sided
product. They sell a kit for $199 but you can buy the ink
seperately, for $50 per ounce!!! I have not tried their ink but
if it works as well as the Staedler ink then it should produce
good results.

General Consulting
12856 Inglewood Ave.
Hawthorne, Ca. 90250-9902

I get the best results if the lines are drawn twice. I do this
by specifying the pen width as slightly smaller that the trace width.
This causes the cad package to believe that it has to trace the lines
twice to get the proper width. The second pass is slightly offset
from the first. I also slow the plotter down to it's slowest
speed, 1 cm/sec. This gives the ink time to flow into a good
solid line.

The plotter that I use has a HP-IB interface. These plotters
are much more common on the surplus market than the async interface
version. I drive it through my parallel port using a special
cable and device driver supplied by Orion Engineering.

>
>Surely this has been tried already. Is it practical?

India ink makes an adequate resist, but it doesn't dry fast enough
so multiple passes tend to smear. The problem is with writing speed.
Most plotters write too fast to get good coverage. This is especially
a problem for narrow traces. For wider traces you can make multiple
passes to fill in, but with narrow traces that usually generates blobs.
Copper doesn't take ink like paper does. I've tried special resist pens,
but they skip badly at plotter speeds. If you can convince your plotter
to slow down to about 1 inch per second, it'll work pretty well.

If there isn't a driver for your plotter in your favorite CAD program,
most CAD package drawings can be imported into Autocad, and if it
ever plotted, Autocad has a driver for it.

I've started just laser printing the pattern on transparencies and
ironing it onto the copper. Works pretty well, and you can do any
slight touchup needed with a resist pen.

What I'd really like is one of those plotters with a milling cutter
instead of a pen. That's the slick way to go, no messy etching, and
lots of nice groundplane.

: Any problems from the spurs ... ? Any thoughts ...?

Lots of spurs lurking about out there on this one. Consider a
clock at 40MHz, used to generate a DDS signal at 10MHz. If it's
exactly 4:1 division, there won't be any jitter on the output.
But if you want 10.000 + or - a little, then most of the time
you divide by 4, but sometimes you divide by 3 or 5, getting to
the MSB. This means that the spectral purity of the output is
very poor.

It may be possible to do something like the fractional-N pll to
provide an incremental analog delay of the square wave edges,
delaying each successive edge by a little more, till you
accumulate a whole clock pulse of delay at which point you
reset the delay, insert one extra pulse, and start the cycle
over again. This would probably be hard to get really right
(good spectral purity).

If you look at this a little differently, it's easy to see that the number of poles & zeros shouldn't be significantly affected. Come up with a pair of filters for quadrature phase that you are happy with for amplitude and phase matching. Add the same zeros and/or poles to both. Then the amplitude and phase matching will be unchanged. However, it should be easier to put the frequency shaping outside the quadrature phase network, since it can then be guaranteed to be identical for both channels. Leave the quadrature network all-pass; if you wish, shape its absolute phase to compensate the frequency-shaping filter. At least, that is how I'd approach it if I were constrained to do it analog.

Chris Elmquist (chrise@comtrol.com) wrote:
: What I'd like to know-- is if the mentioned HR-2600 can be modified for
: 26 to 30 MHz coverage..

Good point Chris.

Remember, there is a one to one relationship in tuning between the
transverter and the transceiver. If the transverter is set up for
a transceiver that tunes from 28 to 30 Mhz, then you will only get
2 Mhz coverage on the conveeted frequency. So if you want full
coverage on 2 meter (144-148) then your transceiver needs to tune
from 4 Mhz. Likewise, for 6 meter (50-54) you also need
4 Mhz coverage.

Therefore, if the transverter is set up to convert 28Mhz to 144Mhz
(or 50 Mhz) then on most transceivers that tune up to 30Mhz, you will
only get 2Mhz band spread (ie 144-146 Mhz or 50-52 Mhz).

Some transverters have a switch that will allow you to change your
band spread.

So before you order the transverter, make sure that you will be able
to tune the freqs that you want to tune.

Howdy. I found out recently that it is legal to run an unlicensed AM staion on a college campus at whatever power you like so long as you do not interfere with other stations that cover that area and the field strength of your signal does not exceed some certain amt 30 meters off campus. So, I figured I'd look into starting one up.

Anyway, what I am looking for is plans or a kit for something to transmit with. I know how to build a very simple AM transmitter, but it is very primitive, and I'm sure my signal would not be very clean or steady. So, if anyone knows where I can get a kit or some plans for an easily built (by a reasonably mechanical type person with a small amt of knowledge of electronics) transmitter, could you point me in the right direction?

Thanks,
Craig.

>is how I'd approach it if I were constrained to do it analog.

I think the key phrase is "shape its absolute phase to compensate the
frequency-shaping filter." I didn't explain the situation I had in mind
very well. Let me try again.

Suppose the system has been realized with a conventional all-pole bandpass
filter such as Chebychev or Butterworth for the amplitude shaping, followed
by all-pass networks to flatten the system's group delay and get the
90-degree phase difference. The 90-degree phase difference and flatness of
group delay are just within certain tolerances.

Now you decide to improve the amplitude response (better shape factor) by
changing the bandpass filter to the elliptic version, with the same number
of poles but additional jw-axis zeros. You try to readjust the all-pass
networks to restore the flat group delay and the 90-degree phase difference
to within the original tolerances.

My conjecture is that this cannot be done without adding more all-pass
pole-zero pairs. If the group delay is within tolerance, the 90-degree
phase difference isn't, or vice-versa.

Also a good point, but I only want coverage from 144.0 to 144.2 or so. Also, Chris may have wanted to cover CB bands with the HR-2600, which I am told is possible.

HP plotters have a command that will slow plotting down to
1 cm per second and I believe Houston Instruments plotters have
a command also. A problem remains when the application issues
a plotter reset before plotting and after you issue your speed
command. A solution is to plot to a file and edit the file
before plotting it.

Maybe the people building CNC drilling machines will be able to do this .. However, a halfway house (still needs messy etching but getting away from the problems with limited resolution of cheaper pens) might be to mill away only the etch-resist.

Spray a clean board with an etch-resistant coating (Letraset protective spray perhaps, or a damp-proofing spray for HT leads) then remove fine lines from it with some sort of replacement pen. The force and stability required to move a cutter that's attacking a thin plastic layer would be much less than that required to mill copper, and there'd be less of a problem with swarf.

I haven't tried this. I haven't even found time to try the etch-resist pen yet, so I don't know how well that's going to work for my application. I notice, however, that Staedtler have changed the design of their pens slightly, and the packaging specifically claims that they're fast-starting. Perhaps they're better than they used to be.

They have, but they're quite expensive for an individual hobbiest. I've also seen homebrew adaptations of regular plotters and Dremel tools. They don't work very well because the plotter mechanism isn't designed to handle the forces needed for milling.

This is a clever idea. You could use a swivel knife as your pen. The resist is likely to come off in curls though, so you probably need to chase it with a whisk brush. At slow plotting speeds, you should be able to keep the work area clear by hand. I think I'll try this out.

Gary

Sorry, I didn't mean the commercial ones : I've seen description here (or in sci.electronics, where this discussion usually lives) from people of those machines. But this is r.r.a.homebrew : there are a couple of people homebrewing CNC drill tables (and talk of offering kits ..), intended for drilling PCBs. These should do the job, but there are areas I'd expect them to have problems :

Not as precise as a plotter, so capable of fairly coarse tracks but not the .025 PQFP pin spacing I'm after.

Capable of more side-force than a plotter, but still optimised for down-force since it's expected that the drill will be up when the head (or table) is moving. This may be a problem if spring pressure is used to reduce backlash in the worm drives, but perhaps milling could also proceed in a direction on each axis that assists the spring rather than works against it.

Needs a very small bit (or an angled bit ?) to make a small gap. I think this came up before, but forget what was said. This is where my suggestion gains a little, since the cutting depth is very small.

==========

From: steve@hi.com (Steve Byan)
Newsgroups: comp.dsp,rec.radio.amateur.homebrew
Subject: adaptive denoising filters for voice
Followup-To: comp.dsp,rec.radio.amateur.homebrew

Dr. Steven E. Reyer, WA9VNJ, and David L. Hershberger, W9GR published a brief tutorial in the September 1992 issue of "QEX", published by the ARRL. Their adaptive denoising filter uses Widrow's LMS algorithm to adapt an FIR filter, using a delayed version of the input signal as the reference signal. They claim that by proper choice of the delay and adaptation time constants, the FIR filter will adapt to a bandpass response around the portions of the spectrum which have a high "short-term" correlation (corresponding to the speech signal), and thus reduce the uncorrelated noise.

Reyer and Hershberger only reference Widrow et al's 1975 paper "Adaptive Noise Cancelling: Principles and Applications" in the Proc. IEEE Vol 63, No.2. I haven't tracked down this reference yet. (Wish I lived closer to a good university library.)

My questions:
1) Do the other denoising products use an algorithm similar to that described by Reyer and Hershberger? If not, what algorithms do they use?

2) Are there any good tutorial papers on this subject? Any important references other than Widrow et al?

3) It occurs to me that an LPC vocoder, such as used in a CELP vocoder, would serve as an effective denoising filter, since it supposedly models the vocal tract resonances. The excitation for the reconstruction filter would be the input (noisy) signal. Is it feasible to extract the LPC

parameters from a noisy signal? Is anyone using this approach?

From: cole@soldev.tti.com (Randy Cole)
Subject: Re: adaptive denoising filters for voice
Date: Mon, 14 Mar 1994 15:16:06

W9GR is on the net and may see your posting.

>My questions:
>1) Do the other denoising products use an algorithm similar to that
>described by Reyer and Hershberger? If not, what algorithms do they use?

There are some that supposedly use a technique you could call "power spectrum gating" or the like. Suppose you compute a long-term average power spectrum. You might convince yourself that this represents a "noise floor". Then you take a segment of the noisy signal, look at the power spectrum, and by some means or another throw away spectral bands that don't exceed the noise floor by some amount.

A grad student friend of mine used this technique 20 years ago and his version
exhibited very noticeable artifacts. Maybe people have thought of better ways
to do it.

>2) Are there any good tutorial papers on this subject? Any important
>references other than Widrow et al?

I dunno. See your (not so local) library :-)

>3) It occurs to me that an LPC vocoder, such as used in a CELP vocoder,
>would serve as an effective denoising filter, since it supposedly models
>the vocal tract resonances. The excitation for the reconstruction filter
>would be the input (noisy) signal. Is it feasible to extract the LPC
>parameters from a noisy signal? Is anyone using this approach?

LPC techniques in general don't handle broadband additive noise all that well. They go to pot pretty quickly for SNR less than 30 dB or so. I'd doubt
that any of those you mention use this approach.

Good luck!

From: sxb@inel.gov (Steve Bryan)
Subject: Re: adaptive denoising filters for voice

Steve,

In article <steve-140394123659@brainiac.hi.com> you write:
>I'm interested in understanding the design of adaptive denoising filters
>for voice communications. There are several manufacturers selling DSP
>denoising filters to the amateur radio marketplace, and apparently some
>commercial units for aviation communications. Some well-known manufacturers
>are JPS Communications, Inc, Timewave Technology Inc, and W9GR.

I own a Timewave DSP-9 with which I am very happy.

>Dr. Steven E. Reyer, WA9VNJ, and David L. Hershberger, W9GR published a
>brief tutorial in the September 1992 issue of "QEX", published by the ARRL.
>Their adaptive denoising filter uses Widrow's LMS algorithm to adapt an FIR
>filter, using a delayed version of the input signal as the reference
>signal. They claim that by proper choice of the delay and adaptation time
>constants, the FIR filter will adapt to a bandpass response around the
>portions of the spectrum which have a high "short-term" correlation

>(corresponding to the speech signal), and thus reduce the uncorrelated
>noise.
>
>Reyer and Hershberger only reference Widrow et al's 1975 paper "Adaptive
>Noise Cancelling: Principles and Applications" in the Proc. IEEE Vol 63,
>No.2. I haven't tracked down this reference yet. (Wish I lived closer to a
>good university library.)

Widrow has published a book entitled "Adaptive Signal Processing". As
of a year ago, it was the only such book that had been published. I own
a copy, but I have only read selected chapters.

>My questions:
>1) Do the other denoising products use an algorithm similar to that
>described by Reyer and Hershberger? If not, what algorithms do they use?

The adaptive filter algorithm is very flexible, and can be used for
all sorts of things. What it does depends on the error signal that you
are providing to the algorithm. I suspect that my DSP-9 uses a
somewhat different approach for noise reduction, still based on adaptive
filtration. The denoiser follows the output of a selectable FIR
bandpass filter, and an optional adaptive notch filter. The adaptive
notch filter is fed a different error signal than the denoiser, and
seems to include more taps in the filter array.

The Timewave documentation is somewhat vague about what the specific
algorithms used are. There is mention of a correlation-based
approach. I think that the peak autocorrelation (not including the
zeroth time lag) of the signal is used to provide the error signal for
adaptation of the denoiser.

>2) Are there any good tutorial papers on this subject? Any important
>references other than Widrow et al?

I think that Widrows book is probably the best on adaptive algorithms
and applications. There is a book that is a compendium of articles that
is edited by Jae S. Lim called "Speech Enhancement" Prentice-Hall signal
processing series, ISBN 0-13-829705-3. It covers other denoising
algorithms as applied to speech signals. The table of contents
categorizes the articles concerned with enhancement of speech degraded
by additive noise under the following topic categories:

Effect of noise on speech communications
Systems based on the perceptial aspects of speech
Systems based on the periodicity of speech
Systems based on an underlying model of speech
Systems that require more than one microphone input
Applications of speech enhancement

There are three other major topics in the book in addition to
enhancement of speech degraded by additive noise, which are

Processing of speech prior to its degradation by additive noise
Enhancement of speech degraded by reverberation
Time scale modification of speech

This book is NOT a tutorial, but does contain many basis articles from
which many subsequent articles in each of the areas have been published.

>3) It occurs to me that an LPC vocoder, such as used in a CELP vocoder,
>would serve as an effective denoising filter, since it supposedly models
>the vocal tract resonances. The excitation for the reconstruction filter
>would be the input (noisy) signal. Is it feasible to extract the LPC
>parameters from a noisy signal? Is anyone using this approach?

This is covered in Lim's book under "systems based on an underlying
model of speech". There are three articles in this section of the book:
"All pole modelling of degraded speech", J.S. Lim and A.V. Oppenheim,
"Linear Predicitive Coding of Speech Signals in a High Ambient Noise
Environment", H. Kobatake, J. Inari, and S. Kakuta, and
"Maximum Likelihood Pitch Estimation", J.D. Wise, J.R. Caprio, and T.W.
Parks. I kind of doubt that any of the filters used for ham radio use
the LPC model approach, since extracting the LPC coefficients is pretty
expensive computationally.

Hope that this helps. Let me know if you have any other questions.

73,
-Steve

: 73, Galen, KF0YJ

I don't know about mail order but you usually can salvage some
feed-through caps from the mechanical tuner section of an old
junk TV. Usually you will find 3 or 4 feed-through caps.

As far as pin diodes go, I've heard rumor of using silicon
rectifier diodes as an ok substitute. Don't use the fast
recovery type. I guess the success of this substitution
is dependent on your frequency of interest. It is more likely to
work at VHF and above.

>models were modifiable I understand... but recent ones were supposedly
>potted. I've never seen one myself...

There is a company called Chipswitch that sells replacement microprocessors for the HR-2600 (2510 and Lincoln too) which will allow the unit to operate from 24.8 MHz to 29.999 MHz and add lots of other features. Great for use with a transverter or if you want to do 12 meters. The chip was about $60 as I recall, and installation was straightforward (though you do have to solder and desolder).

I installed one in mine and it seems to work just fine. Their advertising material claims that some radios may lose PLL lock below 25.5 MHz and they sell a fix for this as well. My 2600 seemed to have no problems all the way down to 24.8 MHz. What I want to figure out now is how to lower the output power so I don't need a huge attenuator between the radio and the transverter.

Their info is:

Chipswitch

Actually, an 8 bit DAC isn't a huge pain to homebrew.

A well-known computer graphics company (I will not mention the name) does
NOT bother with DACs (per-se) in its commercial-grade digital video equipment.
Rather, it simply hangs an R/2R network on the output of an HC chip
(like the 74HC373, 74HC3474 series...)

I have done this as well when building a DDS. The values I used were R=1k
for the R/2R network. I simply used an emitter-follower to drive the output,
but if one didn't really need a LOT of output (i.e. only a couple hundred
mv or so) you can just drop a 75 or 50 ohm resistor across its output and
feed it to the LPF that way.

There are several things to keep in mind, though: The outputs of the HC gates
themselves have finite resistance that should be taken into account. This
resistance is on the order of 30 to 80 ohms (depending on device, temperature,
phase of the moon, etc.) and that amount of resistance should be considered
to be series resistance on the gate output thus you would decrease the corr-
esponding resistors by that much. There just happen to be some standard 1%
values that come pretty close:-)

This sort of DAC isn't ultra-precision, but if you are careful, it actually
has good monotonicity. As you might expect, it's not as temperature-stable
as a "canned" one but if you are driving an LO or something, that's not
particularly important (oops... "using it as an LO, I mean...)

As for using the MSB, I would agree with the assessment that using the MSB
of the chain is a really rotten idea. In fact, those same spurs exist
even with the Sine/DAC arrangement but they are reduced in amplitude by the
amount of available quantization.

I might mention that on the several DDS's I built I had an extra XOR gate left
over. This came in handy for adding another LSB for "free". You can add another
MSB in a similar way with a Flip-Flop, too... Also, by appropriate use
of data latches, you can extend the operating frequency of a DDS using
standard HC logic to 7-8 Mhz for a 24 bit counter but when that is done
the chip count increases and some "QSY" flexibility considerations come into
play.

^^^^^^^^
> AL N1AL

Umm... true. But the overall group delay is affected. There is an offline discussion going on on this. The essence of it is that the finite zeros out of the passband by themselves don't affect the phase (certainly true) but the somewhat different pole positions have an effect of to-be-determined significance. Stand by.

Sounds about right. I've built a number of Ramsey kits of various flavors. The stepping motor driver worked fine. The 20MHz receiver had 3 components wrong and one misdrilled hole on the PC board, but it worked OK. (Why 20MHz? I just needed to see a working circuit with an NE602 at that frequency.) I just built the MD-3 motion detector, which is a 1GHz Doppler radar, and I can't even get it to oscillate. Tried changing the RF transistor; no joy.

Can anybody estimate the spectral distribution of these spurs ?

The far-out spurs are filtered out by the low-pass filter in the
PLL multiplier anyway, so all you have to worry about are the
close-in spurs. It depends on the response time requirements
of the PLL multiplier how much close-in spurs can be removed.

Source record: 118094

Hi,
I am repairing my old DSI 600 mhz counter (timebase died).

The unit displays freq readings even when the input signal is quite small. The readings occuring when input signal is a low amplitude, are usually slightly higher than the real freq or just high and wrong and random. This seems normal for this unit. The Prescaller IC tries to divide by 10 regardless of input signal amplitude.

I would like to homebrew a circuit mod that inhibits freq display any time the input signal is below a minimum amplitude that I would select.

I am looking for any info about how such a circuit is implemented in modern freq counters, what family of circuits are used to be usable at 600 mhz.

Suspect some of the 100 series ECL IC's from Motorola, Philips or Sony may be usable at 600 mhz. Need suggestions where to get these at low cost in small quantities...just enough for this project.

Thanks, Dave
w6mik

...a pile of stuff deleted...

The way we make test PCBs at work is rather simple and more importantly, QUICK.
We draw the pcb artwork using AutoCad (I mostly design microwave stuff) and
then send the file to the laser printer at 1:1. I load the laser with a sheet
of clear acetate and let the printer do it's thing. Bingo, I have a film
positive of my artwork. I then go to the lab and make a contact print on
a piece of PCB that has been sensitized with a photo resist coating. Then
the PCB goes through the normal proceedure of copper etching, cleaning, etc.

This method has allowed us to make PCB artwork with microstrip lines as small
as 7 mil (!) with good results. If you can't load the acetate material into
your laser, you can always print to a piece of paper and then photocopy the
paper onto a piece of acetate. The only problem here is that most photocopiers
do not make perfect 1:1 copies (not close enough for 2.8 GHz microstrip!).

859. Notch filters and audio q

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-09 21:06:00 UTC
From: bill.shymanski@mwcsinc.muug.mb.ca
Message-ID: <1270.596.uupcb@mwcsinc.muug.mb.ca>
Source record: 118099

@SUBJECT:Notch filters and audio quality N
I'm in the middle of building some notch filters for the Morse ID on the
UHF links between our VHF repeaters; the idea is to keep the link ID's
from showing up on the VHF side and disturbing users there.

I'm using a National MF10CCN switch-capacitor filter with two sections
of notch-filter, cascaded, to suppress the 1064Hz Morse. This works
sort-of OK - right now I have the switched capacitor filter set for a Q
of only 10, cutting out a 100 HZ notch centred on 1064Hz. But...how big
a notch can I cut out without degrading speech quality ? Should I go
much smaller - the disadvantage then is that the centre frequency of the
SCF becomes more sensitive to temperature range; I don't want the Morse
showing up on hot/cold days because the oscillator drifted.

The other thing I've noticed is that I still hear the "clicks" produced
by keying the Morse; I guess either the keyers in the repeater
controllers aren't synchronized to the zero crossing, or else there's
some fundamental limitation as to how much I can expect to notch out -
the transient at the start must have frequency components other than
1064 Hz. I suspect the latter; my own 8748-based ID'er also seems
to generate the same clicks, and the way my software works it has to
key only at zero crossings (a dit is 85 cycles of 1064 hz followed
by an equal silent period, at 15 words/minute).

I had hoped for 40 dB of notch suppression but the best I've measured
so far is about 30 dB - probably adequate for our purposes. I also have
some problems with the 100x clock of the switched capacitor filter
leaking through to the output; is this unavoidable or should I revise
my circuit board layout again ? A 2-pole filter made of an LM324 seems
to keep most of the 100khz in where it belongs; hopefully the
transmitters won't attempt to send out what little of the 100khz gets
past.

I found it pretty easy to generate 1064HZ with the 8748 as a square
wave; but this has lots of harmonics. It was only a little more
difficult to make a 6-step waveform and run that through an R-2R
ladder to make a crude D/A converter - the resulting waveform only
has 5th and higher harmonics according to my calculation, making it
easier to filter. If I had enough CPU speed left I could put in an
8-bit D/A and use 255 steps/cycle but then it's hard to get the
1064 Hz frequency bang-on; since it takes the 8748 5uS to update the
output port for each step.

Umm you need to call Ramsey Electronics. They sell AM and FM transmitter
kits etc..They are very good kits and cost only a couple bux $20 etc..
umm i purchased the FM-10 stereo FM kit and it is great.. just need an
amp now!!! so here's the info also there is a newsletter out of berkley
ie FRB - Free Radio Berkley they sell kits and amps also etc etc..

also if you need any more info etc.. i can uuencode a bunch of txtz i
have collected on pirate radio etc etc..

Ramsey Electronics Inc.

863. Definition of "ripple" in filters?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-10 23:08:27 UTC
From: jjw@seastar.org
Message-ID: <Co2GA4.BwJ@seastar.org>
Source record: 118103

What, precisely, is meant by 'ripple' in a filter? IE if I
have a filter that, within the passband, the insertion loss varies
from 2.6db to 1.1db, is this 1.5db of ripple, or .75db?
Also, then, how does one determine the -3db edges? Is that
-3db from the average of high and low within the passband?
I *think* I've built a filter adequate for SSB - 2.5khz wide
with 1.5 (or .75) db of ripple, that's 32db down from the average of
high&low only 600 Hertz away. I'd like to know how to correctly
describe it. Thanks.

Bill:

Instead of generating the Morse code tone with the micro, why don't you just provide an output from the micro that keys an audio oscillator on and off. To me, this would be simpler to code. An audio oscillator can be made from 1 section of a Schmitt inverter section. I recently published an article in QEX about generating morse code in this fashion. This is just my 2 cents worth. Oh yeah, it was the Feb/94 issue of QEX. 73, Nick

In an earlier post, it was mentioned that ironing a laser print on a copier-usable transparency sheet would work as an etch mask.

Well, I tried it this weekend by photocopying on to a sheet of transparency
and ironing that onto the copper. I did no have any pc-board cad capability
and it was faster to just copy the patterns out of the magazine (using the
center of the field on the copier for lower distortion). It worked, kind of.

My question is, what iron temperature was used and was the transparency peeled
off hot or cold? I used 1 sheet of paper between the iron and the transparency.

Schematics are all over the place. The _ARRL Handbook for the Radio Amateur_ has good introductory information on amplifiers. _Solid State Design for the Radio Amateur_ is a classic technical book about radio, including amplifiers.

Of course, this assumes you mean the ham bands. You _do_ plan to use this on the ham bands with your FCC-issued ham radio license, don't you?

The spectral distribution of the spurs in a DDS system can be pretty
easily estimated. It helps to consider the DDS output as a sampled
waveform -- usually a sinewave, but in Alvin's case (using the MSB
of the phase word), it is as if he were sampling a squarewave with
his DDS sample clock.

In the case of a typical sinewave look-up-table (LUT) driving
a D-to-A converter, you can determine the spectral content of
the raw output waveform: a stepwise approximation of a sinewave,
being quantized in both phase and amplitude. No doubt there is
a nice analytical method of deriving the spectrum, but I just
use a long FFT to get it. The are additional dynamic and static
non-linearities caused by non-ideal D-to-A converter characteristics,
but in my work, these haven't been dominant factors. in applications
where extreme spectral purity is important (local oscillators, for
example), you probably shouldn't ignore these.

In the proposed case of a squarewave, the spectrum is easy:
All odd harmonics, dropping linearily with their order (the
Fourier series for a square wave).

Having determined the basic un-sampled spectrum, you then
sample it and see what happens. This is a modulation process,
just like a radio's local oscillator:

Let the desired output frequency be F1, say 1 MHz for example.
Give it an amplitude of 1.0V

The harmonics of the basic waveform have to be accounted for also:
2nd Harmonic = F2, for a square wave, 2 MHz, 0V
3rd Harmonic = F3, 3MHz, 0.333V
5th = F5, 5MHz, 0.2V
(etc, until the amplitudes become insignificant for the application)

Let the DDS sample frequency be Fc, how about 4.096 MHz.
The output will be :
F1, Fc + F1, Fc - F1, 2Fc + F1, 2Fc - F1, (etc)
F2, Fc + F2, Fc - F2, 2Fc + F2, 2Fc - F2, (etc)
(etc)

You have to apply a sinx/x correction to these modulation products as well.

Note that many of the higher-order harmonics, when sampled, will get
folded back (aliased) into the frequency range of interest. When
the sample clock is a multiple of the output frequency, the harmonics
all fall at 0Hz or the desired output frequency, so they don't affect
the spectral purity (as Tom mentions.)

It is interesting that as the output frequency is changed, the higher-order
spurs shift in frequency faster than the fundamental output does. This can
be used to advantage in some applications by applying a pseudo-noise frequency
modulation to the DDS frequency-control word. This smears the spurious signals
across a wider bandwidth without affecting the desired output much. Kinda the
way a carrier is spread out and the narrow-band amplitude is reduced using
spread-spectrum modulation. I haven't tried this myself, though.

I wrote a program to do the number-crunching and show a spectrum-analyzer
type display, to help me when I use DDS techniques to synthesize digital
clocks for tele/data-com equipment. We are extremely concerned with
jitter (short-term variations in clock phase/frequency) in these products,
so my program applies any filtering I specify to the spectrum, then sums
the amplitudes of the spurs and calculates their impact on the zero-crossing
of the desired output signal -- thus giving me a predicted jitter for any
clock relationship and filter shape.

Unfortunately, right now I have a canned waveform (a sinewave with 256 phase
steps, 32 amplitude steps), so I can't run the squarewave example. If there
is interest, I could hack it to make it more general...

So, in conclusion: What Tom said. Unless you have a carefully chosen frequency
ratio, the high-order harmonics of the sampled square wave (the MSB) will sneak

back and bite you.

: controllers aren't synchronized to the zero crossing, or else there's
: some fundamental limitation as to how much I can expect to notch out -
: the transient at the start must have frequency components other than
: 1064 Hz.

That's right. Any modulation (including on-off keying) widens the bandwidth.
You can help the situation by "softening" the keying of the CW ID'er.
You can do that eigher by slowing the rise/fall times or by running
the 1064 Hz signal through a narrow band-pass filter.

Another solution is to use a DSP-based notch filter like the W9GR unit.
It automatically finds all coherent carriers in the audio passband and
notches them all out simultaneously. That way, you wouldn't have to
worry about frequency drift between the oscillator and notch. It also
automagically removes DTMF tones, whistles, etc. It won't eliminate
the key clicks, though, because it takes a few milliseconds to
acquire each tone.

872. Intermodulation and Switching Diodes

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-12 01:56:46 UTC
From: drew@trl.oz.au
Message-ID: <drew.118.0@trl.oz.au>
Source record: 118112

A recent posting asked about the possible intermodulation effects of using diodes to switch front-end filters in a planned receiver project. Ulrich Rohde's "Recent Advances in Shortwave Receiver Design" (QST 'Nov. '92)-(also follow-up discussion in Technical Topics, Radio Communication Feb '93) was pointed.

Here is another topical paper on the subject:

"Intermodulation Properties of Switching Diodes"

Dr. (Eng) Jochem Jirmann, DB1NV, VHF Communications, 1/94.

Includes schematic of his test set up, graphs of intermod. products for second and third-order, current bias levels vs. intermod. interval for typical European diodes and summary of results. Also a brief discussion on intermod. and front-end inductances.

His bibliography reference is;

"Improvement in Intermodulation Behavior of Modern Short-Wave Amateur Receivers"

Dr J. Jirman and W. Hercher, DL8MX, VHF Comms 1/93.

Green Card Lottery 1994 May Be The Last One!
THE DEADLINE HAS BEEN ANNOUNCED.

The Green Card Lottery is a completely legal program giving away a certain annual allotment of Green Cards to persons born in certain countries. The lottery program was scheduled to continue on a permanent basis. However, recently, Senator Alan J Simpson introduced a bill into the U. S. Congress which could end any future lotteries. THE 1994 LOTTERY IS SCHEDULED TO TAKE PLACE SOON, BUT IT MAY BE THE VERY LAST ONE.

PERSONS BORN IN MOST COUNTRIES QUALIFY, MANY FOR FIRST TIME.

The only countries NOT qualifying are: Mexico; India; P.R. China; Taiwan, Philippines, North Korea, Canada, United Kingdom (except Northern Ireland), Jamaica, Domican Republic, El Salvador and Vietnam.

Lottery registration will take place soon. 55,000 Green Cards will be given to those who register correctly. NO JOB IS REQUIRED.

THERE IS A STRICT JUNE DEADLINE. THE TIME TO START IS NOW!!

For FREE information via Email, send request to cslaw@indirect.com

I don't happen to have the information in front of me but i noticed,
and bought, an interesting item from Digikey the other month.
it's something called the Toner Transfer System which consists of
specially formulated sheets to laser-print onto and then iron onto a
pc board for immediate etching. i have not had the chance to actually
try this yet but they did seem to readily achieve double traces
through 100mil through holes.

it also contains instructions that mention various fine points
including carefully ironing (pretty big iron to compensate for large
heat sinking of copper clad board) and "super-charged" toner
cartridges that they highly recommend.

they also sell various pieces of equipment such as a highly modified
lamenating machine that does the ironing for you. not too cheap
though.

i'll get the name, # etc. later but try your digi-key catalog near the
homebrewing section of course.

>then send the file to the laser printer at 1:1. I load the laser with a sheet
>of clear acetate and let the printer do it's thing. Bingo, I have a film

etc ..

Yes, I appreciate this is a popular and reasonably successful method.
The plot-on-PCB scheme, though, is deliberately intended to (a) use a cheap second-hand plotter instead of an expensive modern laser printer, and (b) avoid the photographic stage. As Gary said, it would be even better to avoid the etch stage too.

It isn't necessarily the best system, and if you have a laser printer and no plotter, it may well be better to use that. Homebrew (IMHO) is all about doing it with what's in the garage or the junk sale, rather than buying anything new ! Extra points if you don't have to rely on the goodwill of your employers, too.

Having said that, I've tried making artworks on a laser printer and had mixed success - the lines came out 'fluffy' and with holes in them, as though the toner had shrunk together through surface tension. I think this is a problem with the mobility of toner particles on plastic film as opposed to paper, and suspect that some toner/printer/film combinations work better than others. I'd be interested to know what works best.

the name of the company for this Toner Transfer System is
DynaArt Designs
(805) 943-4746
they have a real neat little catalog for the homebrew type.

what sounds intrigueing is how they say that the process of ironing
the ink from the transfer onto the PCB anneals the gunk so that minor
holes created by imprefect laser printing can get melted over. they
also mention how one client used acetone i think to harden the surface
of the ink for better etching and to fill in micro-holes.
also they mention attaching a big chunk of aluminum to an iron to
distribute the heat better and i feel to increase the iron's heat
capacity so the PCB doesn't cool it down so quickly.
there were other interesting tid-bits in the catalog also.

still have yet to try this paper myself.
maybe in a week or two. (or three, or four....)

> You have to apply a sinx/x correction to these modulation products as well.

I had a program for calculating high order IMD products in amplifiers
and mixers. I modified it a bit to handle the amplitude distribution
of the DDS output frequency harmonics and applied the sinx/x correction
to the spurs. Now it is easy to try out some interesting cases.

> Note that many of the higher-order harmonics, when sampled, will get
> folded back (aliased) into the frequency range of interest. When
> the sample clock is a multiple of the output frequency, the harmonics
> all fall at 0Hz or the desired output frequency, so they don't affect
> the spectral purity (as Tom mentions.)

On the other hand, if you stay away from these frequencies (at least a
few kHz away from them), the spurs are distributed far away from the
output frequency and no close-in spurs are present.

Assuming we need a synthesiser for the 144 - 148 MHz band with 1 Hz
steps. If we use a PLL multiplier with a fixed by 100 multiplier, we
need a DDS reference capable of producing 1.44 - 1.46 MHz in 0.01 Hz
steps. A 29 bit DDS (MSB output only) clocked at about 5.369 MHz
could do the job. I checked the whole tunning range, and I couldn't
find any spurs (at least 20th order or less) in the range 1.2 - 1.8 MHz.
A modest band-pass filter should be enough to prevent the PLL multiplier
to lock on these spurs below 1.2 or above 1.8 MHz.

The PLL loop bandwidth would typically be a few kHz and as the closest spurs are at least 200 kHz from the reference frequency, it should be easy to filter it out in the PLL loop filter.

> So, in conclusion: What Tom said. Unless you have a carefully chosen
> frequencyratio, the high-order harmonics of the sampled square wave
> (the MSB) will sneak back and bite you.

Yes, this happened to me, when I tried to expand the tunning range to 1.4 - 1.5 MHz.

In Electronics World+Wireless World October 1992 on page 843 there is a similar system. The DDS is used for fine tunning on a very narrow band near 10 MHz and it is used as the reference for the PLL producing outputs in VHF or UHF. The PLL that has a variable multiplier for coarse tunning. As the multiplier is varied, the step size will also vary. If you need a constant step size across the whole VHF/UHF output range, a few more bits are required at the DDS and only those input words are used that approximate the required step size.

I am wondering how to measure an output power greater than 1kW on VHF using a
BIRD 43.
There is a BIRD slug available but that's a 2.5kW peak one.
Does anyone know the subtile meaning about this 'peak' notice.

: What, precisely, is meant by 'ripple' in a filter? IE if I
: have a filter that, within the passband, the insertion loss varies
: from 2.6db to 1.1db, is this 1.5db of ripple, or .75db?

1.5 dB is right. The term "ripple" comes from the fact that an
ideal chebyshev filter (one of the more popular designs) has
an almost sinusoidal reponse in band.
: Also, then, how does one determine the -3db edges? Is that
: -3db from the average of high and low within the passband?

Generally from the peak in band point, though the definition is
not set in concrete for anything but butterworth type filters.

>capacity so the PCB doesn't cool it down so quickly.
>there were other interesting tid-bits in the catalog also.

The problem with both of the toner transfer systems that I tried,
transfer film and sugar paper, is that the traces mush outward as
you iron them onto the copper. If your design has fairly close
trace spacings then they will short. A device that applied a very
even pressure at a precise temperature would probably work well but
an iron is just too crude for good results.

A technique that I tried and got better results on small boards
is to use ordinary copier paper. It does not have the problem
with trace mush. Try this;

* Iron your pattern onto the board with the iron temp. set to max.
* Lift the iron off the board for a second. Put a paper towel
saturated in water on the paper and put the iron down as fast
as possible.
* Iron the wet towel for a few seconds. Do not dry out the water,
it should still be boiling when you are done.
* Put the board with the paper still attached in a pan of water and
leave for a few minutes until the paper is completely soaked.
* Rub the paper with your fingers under water so as to disintegrate
the paper.
* Inspect the board for remaining paper between close traces. You
can use a tooth brush or tooth pick to open up blocked areas.

You will notice that the toner is securely attached to the copper
but has fibers from the paper still imbedded in it's surface. This
will not bother etching so long as they are not matted onto the
copper.

The purpose of the wet towel is to drive steam into the paper
causing the paper to expand. Without this step the paper contracts
as it cools and pulls the toner off the copper.

Good luck, Pete.

What you need is a Schmidt trigger circuit near the input stage, at least before the counter ICs, if after the prescaler. For a 600 MHz counter, that would be a 60 MHz Schmidt. If it has to be threshold adjustable, the easiest way is to implement it with discrete transistors. Any good VHF switching transistor should be fine for the job. Just set the bias threshold wherever you want readings to commence.

80 meter 1/2-wave Zepps present a difficult impedance to match at 15
meters. An old rule of thumb flattop length for all the HF bands is
105 feet. That will present a feed impedance within the range of most
good open wire balanced tuners on all bands.

If you're using an unbalanced tuner and a balun on the output, then
all bets are off. That often doesn't give you a large enough (efficient)
matching range for an all band flattop. Use a balanced tuner, and if you
must, use a 1:1 balun on the *input* side of the tuner where it'll work
efficiently. There are tuner topologies that do the unbalanced to balanced
transform internally so you don't need a balun at all, but they're typically
a bit more complex and require more unusual components such as swinging
links. (These are actually great if you don't mind the mechanical challenges
involved in building them.)

Use an iron set on "cotton", or it's highest setting whatever that's
called. I iron the transfers on with an old Tee shirt as a buffer.
Use a *lot* of pressure on the iron. Wait until it cools before peeling
off the film. The copper must be *very* clean for this to work well,
scrub with Comet before doing the transfer.

Don't know about Tech-2000, but TEC-200 film works OK. But as you note,
Avery overhead transparency film works fine, and is cheaper and easier
to get.

I have used this to make prototype double sided pcboards.

I got better results by printing pattern to paper then
shooting with accurate photocopier. You can lay the clear
page over top of the original to check for accuracy.

I was doing double sided boards. The biggest problem I had was
protecting the toner layer until I got the "Iron ons" home.

I used wifes standard steam Iron.

Drilling the holes was no joy either. For prototypes its good.
If you want to make something double sided, & through hole
I would recommend Ironing on 1 side, drilling holes In the corners
and using the holes to line up on for the second side.
You WILL HAVE to use a lacquer pen to touch up scratches & holes
& lift backs before etching. But it beats hand drawing the thing.

I think that if you are making more than 5 of the same, use
the photographic process.

David DiCarlo (r14793@waccvm.sps.mot.com) wrote:

: Well, I tried it this weekend by photocopying on to a sheet of
: transparency and ironing that onto the copper. ...

I'm surprised nobody mentioned the ready-made kit you can buy
specifically intended for this application. It uses a
specially-coated paper so that after you iron it onto the PC board
the paper soaks off in a pan of water, leaving the toner behind as
resist. You then etch the board in the normal way.

The pattern can be laid down on the paper using a photocopier
or laser printer.

The only tricky part is that the board must be completely clean and
scoured with fine steel wool. The steel wool seems to roughen the
copper so the toner sticks better. Another trick is to soak the
board with the paper side down. Otherwise, the paper can pull off
some toner as the paper floats up.

: My question is, what iron temperature was used and was the transparency
: peeled off hot or cold? I used 1 sheet of paper between the iron and the
: transparency.

Seems like the hotter the better. I haven't had any trouble with
toner smearing or widening of the traces.

I bought my kit (with 5 sheets of 8-1/2 x 11" paper) for $12.95 from:

Pete, the length really doesn't matter as long as your antenna tuner can
give a conjugate match. 100-105 ft. is popular. My 88 ft. works just fine
on 75m. It should be at least 3/8 wavelength on the lowest transmit freq.

The problem with attempting to measure CW power greater than 1 kW with
a Bird 43 at VHF is that RG-8 sized line isn't rated to carry more power
than that at VHF. To measure higher power, you need a thruline meter with
a more capable thruline section. Dielectric makes thrulines for up to at
least 100,000 watts at VHF, but we're talking 8 inch diameter rigid line
sections now. Still, Bird has made higher power slugs for the 43, I have
an old pair of 10 kW elements. I think they stopped selling them because
too many line sections got fried.

It's quite possible. Conversion of commercial and military gear to ham frequencies is common. Moving commercial VHF-high gear to 2 meters is popular.

Whether your particular radio will work effectively on 2m is a good question. It depends on the particular radio. Post the make, model, vintage (if possible) and serial number (if possible) to rec.radio.amateur.equipment and it is fairly likely that someone will be able to tell you if the conversion can be done. If there are any option boards added to the gear, mention them, too. They can be important.

If you decide to try the conversion, the thing you need most is a service manual for the radio. That is usually available from the manufacturer.

It is often get to hire a commercial radio shop to retune the radio into the ham bands, if you don't want to do it yourself.

I would say that a properly filled-in FCC form 660 is even more
important. That is an FCC license, which is required to transmit on
the "ham".

>Pete, the length really doesn't matter as long as your antenna tuner can
>give a conjugate match. 100-105 ft. is popular. My 88 ft. works just fine
>on 75m. It should be at least 3/8 wavelength on the lowest transmit freq.

An extended double Zepp provides the maximum gain at a specific frequency.
This is like a dipole but has a 5/8 wavelength wire on each end of center
instead of 1/4 wavelength. Its two 5/8 wavelength, end-fed antennas in
co-phase in other words. About 28 feet on each side for 15 meters.
It will give good gain with a sharp pattern in the favored direction.
This may be preferable to the split up clover leaf pattern of the 105'
G5RV on 15 meters which is much less predictable but still may be too
selective.
This antenna could be extended a couple more 5/8 wavelengths with 1/4
wavelength shorted stubs of ladder line. It will probably load okay
on all other bands with a tuner similar to G5RV or extended double Zepp.
Maybe put traps or capacitors across the 1/4 wave stubs for lower freq
use?

Hi:

I'm attempting to make a very broadband synthesizer in the VHF range and I'm looking for some tuning diodes with LARGE tuning ratios. If anyone has any suggestions I'd be very interested.

So far I've gotten 80 MHz to 180MHz with a fairly linear tuning curve. Beyond this the VCO response flattens out. I've got the system running now by misusing hyperabrupt low frequency varactors. These have two problems. Their Q is pretty horrible until you get a fair amount of reverse bias on them. Most are made over a 12V operating range. This gives some pretty massive VCO gains. I'm ideally looking for a high tuning ratio capacitor made for the VHF range. I also wouldn't mind a larger voltage operating range.

Thanks in advance for any advice.

I saw an VCO in RF ??? 1990 sometime that used an electro-magnet to change the
inductance of a coil on a ferrite Coil. It gave a great deal more range than
capicators. Sorry about not rembering the name of the magizine It's a monthly
publication well known and I am pretty sure the editors name is Gary.

Of all the things I've lost I miss my mind the most.
Good luck

Hi nam, I did some vcr tuner tinkering a while ago, varactor diode tuning type, what they do here is use a band switching system, diode switched inductors I think, and then retuned the varactor to give a wider range. If you are using this as a 1 channel at a time synthesizer this could perhaps work for you. If you want a single band sweep for spectrum analyser or spread spectrum than this may not work for you.

I had the same problem with an FX-440 kit. I noticed that the problem was the worst if the board was out of the case and better when it was sitting in the case. I then started poking around on the board and found that pushing down around on the board, I could make it go away. I then bolted it tightly into the case and the problem went away on most frequencies.

I still don't have the transmitter working correctly. People report that they hear the first syllable or two correctly, and then just a dead carrier. A scanner next door receives every word. I've tried two frequency counters, I think it's on frequency. I've tried varying the deviation in small increments from one end of the pot to the other, with the same results. This is about the point where my VHF/UHF skills and equipment give out.

I had fun building the kit, but I don't think I'd get anything this complex from Ramsey again.

From: mac@cis.ksu.edu
Message-ID: <mac.766420641@depot.cis.ksu.edu.cis.ksu.edu>
Source record: 118052

I recently built a 6L6 CW xmtr of rather standard design, and, while it works OK on 80 meters, it chirps like a bird on 40 and above. The power supply is hefty and well-regulated, so I'm pretty sure that a "soft" supply can't be the problem. Besides, a t about 15 watts, I'm not pushing any performance envelope. The chirp is consistent over tube and xtal changes.

My current guess is that maybe a capacitor is heating, but I haven't started swapping them out yet. Does anyone have another idea?

Changes: new mailing lists, .packet rmgroup, and .policy updates

(Note: The following is reprinted with the permission of the author.)

This message describes the rec.radio.amateur.*, rec.radio.cb, rec.radio.info,
and rec.radio.swap newsgroups. It is intended to serve as a guide for the new
reader on what to find where. Questions and comments may be directed to the
author, Jay Maynard, K5ZC, by Internet electronic mail at
jmaynard@oac.hsc.uth.tmc.edu. This message was last changed on 18 September
1993 to add the mailing lists for the new rec.radio.amateur newsgroups, to
note the rmgroup of rec.radio.amateur.packet, and to officially retire some
(in)famous threads of discussion on rec.radio.amateur.policy.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list
for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions
were held on the mailing list, and sent to the mailboxes of those who had
signed up for it. When the Usenet software was created, and net news as we
now know it was developed, a newsgroup was created for hams: net.ham-radio.
The mailing list and the newsgroup were gatewayed together, eventually.

As the net grew, and as packet radio came into vogue, packet discussion began
to dominate other topics in the group and on the list. This resulted in the
logical solution: a group was created to hold the packet discussion, and
another corresponding mailing list was created as well: net.ham-radio.packet
and PACKET-RADIO, respectively.

These two groups served for several years, and went through Usenet's Great
Renaming essentially unchanged, moving from net.ham-radio[.packet] to
rec.ham-radio[.packet]. Readership and volume grew with the rest of the
network.

The INFO-HAMS mailing list was originally run from a US Army computer at
White Sands Missile Range, SIMTEL20. There were few problems with this
arrangement, but one was that the system was not supposed to be used for
commercial purposes. Since one of hams' favorite pastimes is swapping
gear, it was natural for hams to post messages about equipment for sale
to INFO-HAMS/rec.ham-radio. This ran afoul of SIMTEL20's no-commercial-use
restriction, and after some argument, a group was created specifically
```

for messages like that: rec.ham-radio.swap. This group wasn't gatewayed to a mailing list, thus avoiding problems.

While all this was happening, other folks wanted to discuss other aspects of the world of radio than the personal communications services. Those folks created the rec.radio.shortwave and rec.radio.noncomm newsgroups, and established the precedent of the rec.radio.* hierarchy, which in turn reflected Usenet's overall trend toward a hierarchical name structure.

The debate between proponents of a no-code ham radio license and its opponents grew fierce and voluminous in late 1989 and 1990. Eventually, both sides grew weary of the debate, and those who had not been involved even more so. A proposal for a newsgroup dedicated to licensing issues failed. A later proposal was made for a group that would cover the many recurring legal issues discussions. During discussion of the latter proposal, it became clear that it would be desirable to fit the ham radio groups under the rec.radio.* hierarchy. A full-blown reorganization was passed by Usenet voters in January 1991, leading to the overall structure we now use.

After the reorganization, more and more regular information postings began to appear, and were spread out across the various groups in rec.radio.*. Taking the successful example of the news.answers group, where informational postings from across the net are sent, the group rec.radio.info was created in December, 1992, with Mark Salyzyn, VE6MGS, initially serving as moderator.

In January, 1993, many users started complaining about the volume in rec.radio.amateur.misc. This led to a discussion about a second reorganization, which sparked the creation of a mailing list by Ian Kluft, KD6EUI. This list, which was eventually joined by many of the most prolific posters to the ham radio groups, came up with a proposal to add 11 groups to the rec.radio.amateur hierarchy in April 1993. The subsequent vote, held in May and early June, approved the creation of five groups: rec.radio.amateur.digital.misc (to replace .packet), .equipment, .homebrew, .antenna, and .space.

The Current Groups

I can hear you asking, "OK, so this is all neat history, but what does it have to do with me now?" The answer is that the history of each group has a direct bearing on what the group is used for, and what's considered appropriate where.

The easy one is rec.radio.amateur.misc. It is what rec.ham-radio was renamed to during the reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize

this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, should be removed by September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is now rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there.

The first reorganization added two groups to the list, one of which is rec.radio.amateur.policy. This group was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The other added group is rec.radio.cb. This is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently Mark Salyzyn, VE6MGS. The email address for submissions to the group is rec-radio-info@ve6mgs.ampr.ab.ca. Inquires and other administrivia should be directed to rec-radio-request@ve6mgs.ampr.ab.ca. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas,

commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

Actually, 80 to 180 MHz. is fairly respectable; it's over an octave.
When I worked for Zeta Labs, we used to use Motorola MV1401's with
MC1648 VCO IC's to routinely get 50 to 150 MHz. tuning range (with
some design margin). You can also defeat the AGC on the 1648 and
build a 100 to 300 MHz. VCO if you're careful. Since a 3 to 1
frequency range requires a 9 to 1 capacitance range, you won't be
able to do much better than that, because 9 to 1 is getting up near
the state of the art in tuning diodes. At the most you might get
16 to 1, which would give you 4 to 1 tuning range.

We also had a Colpitts oscillator that tuned from 125 to 300 MHz. using
MV209 diodes. The trick here was that both the collector-to-emitter
capacitor and the base-to-emitter capacitor were tuning diodes. That
way the feedback was fairly independent of the tuning frequency.

I tend to agree with other posters that if you're not building a
sweep generator that really needs continuous tuning, it's probably
easier to "wimp out" and use multiple VCO's to cover the range
or put in switched inductors to give a single VCO multiple ranges.
The HP8662 does that, so you would be in good company.

Required by the overly oppressive legal system that is.

But you still want to get a manual as many of the business radios
won't tune that far out of their 'native' band without mods.

Do you key the oscillator? Chirp can sometimes be cured by changing
the design so that the oscillator runs continuously when in transmit
mode and only the driver and/or p.a. are keyed.

Also, if you are using frequency multiplication so that 80 meter
crystals can be used on higher frequency bands, you will find
that this can accentuate chirp. Try using only fundamental
crystals for the band of interest.

919. Need info on 'Miller #2002 coils... help!

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-15 23:25:23 UTC
From: pkinnes@csupomona.edu
Message-ID: <1994Apr15.152523.1@clstac>
Source record: 118063

Sorry if this is an FAQ, but I couldn't find a copy (skimmed through),
and it's semi-urgent that I find out soon.....

I need to find a 'Miller No. 2002' coil for a low-power transmitter a
friend (without net access) is building. Any information would be helpful, as
would addresses, or equivalences, etc.

It's not life-or-death urgent, though we are on a bit of a time
schedule, so early replies would be appreciated greatly...

Tnx!

920. RS232 help

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-16 03:46:58 UTC
From: bon@paradox.win.net
Message-ID: <115@paradox.win.net>
Source record: 118059

I'm working in a project where I have to communicate a certain machine with a host for calibration purposes. A 3 wire RS-232 interface is used. While I can commnicate from a terminal with the machine, I have tried unsuccessfully to write a C-subroutine for that purpose (further analysis shoul be done in the host).

I have a Borland C++ compiler. I tried the functions bioscom and _bios_serialcom as defined in an example in the real time library. A transition of the RTS line after hiting a key is all what I can see.

I got some subroutines from the book "serial communications programming in C and C++" that I tried up too with no success (Even a simple terminal emulator based controlling the BIOS by passing some parameters to the AH register after request INT14 doesn't work.

Finally I tried using some asm. RS232 drivers that I got (the source I believe never used them) in a similar schema to the INT14.

This is becaming too frustrating!!!. I don't need really a interrupt driven channell (just 2400 or less bauds are fine) . Sending few commands to the machine and receiving some data from several ADC is all the activity of the port.

Does somebody have a couples of proved subroutines that I could use ?. You can E-mail the source code UUencoded to my address if that is the case.
Really appreciate, 73 de JB, KB5UWZ.

Maybe... Usually it is, but why take chances. Just use your voltmeter (or
an LED with 1K in series) and find out for sure.

I have come across some old subminiature tubes. They are 5 wire (yes, no pins actually wires!!) They look to be triode and I suspect they are from the era of the tube-type walkie talkies. They are direct drive filaments (no cathode) and I haven't the faintest on the specs (plate voltage, plate current, fil.etc)

I suspect the filament is about 1.5v and plate maybe 22.5 or 45v. am I close? I don't think there were too many types perhaps someone would be kind enough to email me some info. They would make a fun QRP project. Thanks in advance, GARY. N2KTY

Don't think it's heating capacitors -- values would have to change very fast to produce chirp, though they'd surely account for slower drift.

I'd carefully monitor the high voltage key-up and key-down. Maybe a regulator is bad, and it _sure_ sounds like a power supply problem.

> Thanks for the advice. 73 Bill AA5ZQ

Various handbooks and other QRP publications have good plans for QRP watt meters. I'm using the MFJ971, which seems to work well, and has the added advantage of the typical MFJ cross-needle meter, providing simultaneous forward power, reverse power, and SWR measurements. A lot of people would probably say that a Byrd watt meter with appropriate, low-power element would be the most accurate.

I find QRP LOTS of fun; it's like recovering your lost youth, when every contact was exciting. I suspect, though, that QRP is most enjoyed by folk who have already done a lot of other kinds of hamming, so that they get that return-to-the-simple-pleasures effect.

I don't chase awards, but believe ARRL and whoever else just takes your word for output power. It's just a hobby, after all; who would you be cheating but yourself?

Cheers & 72 (QRP for 73)

929. Searching for 450 MHz Power transistor !

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-17 11:02:51 UTC
From: mattis@elixir.e.kth.se
Message-ID: <2or50r$ekd@news.kth.se>
Source record: 117969

Hi !

I am rebuilding a E.F. Johnson MT-9100 mobile telephone to be used for the 432-438 MHz amateur band. It works quite well except for the power-amplifier which seems to have a broken transistor.

Unfortunately these transistors (actually all in the unit) has E.F. Johanson proprietary numbers on them, and there is no translation table into "normal" numbers.. However, one can conclude who has manufactured them.

Please could anyone help me translate these E.F. Johnson numbers into real numbers:

E.F. Johnson # | Manufacturer | Description in partlist | Used as | Notes

4019 Motorola 1 W UHF transistor Class-A TO39
4069 Thomson 2 W UHF transistor Class-C 1)
4061 Motorola 5 W UHF transistor Class-C 2)
4068 Motorola 15 W UHF transistor Class-C 3) 4)
4027 Motorola 45 W UHF transistor Class-C 3)

Notes:

1) Package type : Surface-opposed-emitter.
2) Package type : Surface-opposed-emitter stud mount.
3) Package type : Sorry I don't know the name, it is mounted to the heatsink with two screws. It has 6 connections, 4 of them emitter and the rest collec and base, Motorola calls it 316-01..
4) In one of the units I convert this one is marked MRF641.

Also, where (in the US or in Europe) can I order smaller quantities of the above transistors ? (One distributor here in Sweden could supply me with anything provided that I ordered at least 25 parts...)

Thanks in advance !

/Mattis

Subject: Chirp in a CW transmitter...

Hi, I remember an old timer telling me, a long time ago, that single tube
crystal controlled transmitters had problems with the crystal heating. Altho,
a 15 watt oscillator might very well have problems with cap heating, too.

Did i understand u right? Is this the infamous single tube crystal controlled
transmitter, from years and years ago, that u have built?

The BAYCOM Modem will hook to a Mac.. the rest of the TNC process
gets done in the Mac itself. There's schemtics, drivers etc on many
LLBBS for this.

The LTC1099 is a High Speed 8-bit A/D converter wih a built in
sample and hold. Linear Technology is the manufacturer.
You can call to Linear Tecnology 408-432-1900 to get a list of
distribuitors.

From: jbaker@halcyon.com
Message-ID: <jbaker-180494145014@bellevue-ip16.halcyon.com>
Source record: 117975

Does anyone have experience using IEEE 802.3 "thicknet" cable for antenna feeds?

I am thinking about using it for HF longwire antenna leadin from Balun. It is bright yellow, 50 ohm, well sheilded (two foils and 2 braid layers), has one 12 ga. solid center conductor, attaches easily to PL-239's. Plus I have a bunch otherwise going to waste.

Seems like the perfect stuff but I thought I might save myself some grief if my plans are doomed for some reason I don't see.

Thanks for any input.

>would be a 60 MHz Schmidt.

The best bet is a Schmidt trigger, but it needs to be *before* the pre-scaler (the pre-scaler *is* a counter). Typical ECL flip-flops act transparent when the clock input is balanced, turning the input stage of your pre-scaler into a ring oscillator when the input signal is centered.

A cheap Schmidt can be made using a fast ECL (10KH, ECLiPS, etc) line reciever with a resistive divider from the output to the positive input to provide hysteresis. Two such circuits in a row is somewhat better.

As a "quick and dirty" fix, though, you could just add a little DC offset to the counter or pre-scaler input. (If the counter input is AC coupled, the DC offset needs to be inserted after the AC coupling, so that the pre-scaler IC sees the offset.)

- Dan Knierim

A tough one!

Most frequency counters these days use proprietary chips. You can't get them easily; they're made just for the counter manufacturers.

There are some prescaler chips you can still get. Unfortunately, they're designed for division ratios like 64 or 256, which won't mesh well with your existing counter design. The 11C90, which was the popular /10 prescaler that was used in most of the 600MHz designs of the late 1970's through the 1980s, isn't made any more.

The counter article in the current edition of The Radio Amateur's Handbook goes into this, in the process of explaining why they're only offering a 60MHz counter design these days.

: thinking of building one for an amp. Thanks in advance ... Ken WL7IR

Yes, a simple diode detector will do fine for detecting RF
and triggering a sequencer. However, I prefer to put a
current limited DC voltage on the coax instead. This is
even easier to detect.

This works a lot better on SSB/CW, because it isn't
necessary to incorporate a timing delay to keep the
amplifier in transmit during short pauses. The delay
is often too short when you are talking and too long
when you want to listen.

I use a sequencer to assure the antenna is hooked up
before the amplifier is ready to put out power.
Some amplifiers don't like to see an open circuit.
I think relays last longer if you don't switch
them while many watts of RF is applied.

Myron, give us a few more details. Do you key the oscillator? How? All oscillators chirp when keyed from non-oscillation into oscillation... it's just that some come up to steady state so fast a human ear can't hear the chirp and some are slow enough to hear. Cathode keying is not the way to go. Grid block keying works well especially if you allow a very low level of oscillation when the key is up and a high level of oscillation when the key is down. That gives the oscillator a head start.

Use a Mitel 8870. It is the standard of the telephone industry. It
provides a 4 bit parallel out with a strobe that is perfect for what
you want to do. It decodes all 16 DTMF tone pairs and costs about
$10 bucks. Good Luck, Nick

Works great. Extremely low loss, very rugged and handles being left
outside better than most conventional cables. Be careful using old
Ethernet lines, though, if they've got vampire tap holes left on them.
At the very least, seal them up with RTV. Water will get into them and
you will find interesting line problems.

The TARGA (Tandem Amateur Radio Group of Austin) hamshack is located
about ~150 feet (via cable tray) from where our roof mounted antennas
are mounted. The local building code requires plemtum rated cable.
We used plentum rated ethernet cable (free) to connect both our HF and
VHF rigs. I`m sure the loss is high on 440 but on 2 and HF we seem to do reasonably well
with it. Surely no reason to throw it away.

Our Company president (a well known 6 meter and EME ham) when visiting last month suggested
that we punch a hole thru the wall and avoid the long cable runs. I guess if he said its
ok...Anyone know a good way to punch a 3" hole through 18" of concrete, rock and steel?

James,
I would not recommend using EtherNet cable for use on a transmitter. Sure
it is
very good cable with low loss. However, if you will notice, probably
stamped
on the side of the cable is "50 Volts MAX" or something like that. If you
have
any of the "standard" rigs on the market that will put out 100 or so watts
you
will quickly burn through the cable insulation. If the impedance of the
cable
is 50 ohms then by Ohm's law you would be limited to about 50 watts.
P=EI, I=E/R so P=(E*E)/R so if you are limited to 50 volts then:

P=(50*50)/50 so you would be limited to 50 watts.

My impression is that the Thick-LAN cables that have this stamped on them have it as a safety/regulatory thing for use in the intended application, and that it has nothing to do with the actual ability of the cable to handle voltage. We often rate inputs to instruments at 40 volts maximum, not because that's the most they can stand but because to rate them higher would require jumping through all sorts of hoops, and higher voltage is really unnecessary in the application.

Does anyone out there have evidence to the contrary? Has anyone actually zapped some of it by running a few hundred watts at HF at reasonable SWR? (I _know_ there are folk out there using this stuff for transmitting...)

BTW, I have some which is not marked that way, and the catalog listing for it similarly is silent on voltage rating. In what way is the insulation _so_ different from that in rg8-type foam insulated cables, which may be rated for well over 1000 volts?

Dose anybody has experience of making the Doppler direction finder??
Which has 4 or 8 fixed vertical antennas, and gives bearing of 360 degrees
in digital with 1 degree precision??

I am thinking to make one for my experiment. Although it is quite popular
in communication field, such as FAA(for air crafts) or police(Lo-Jack), I
could not locate any article or source of a Doppler Radio Direction Finder.

If you know something about this, please let me know!! Is any article
available on a certain magazine, electric book(?) on internet or diagrams of
it??

Your advise, comment, and anything related to a Doppler Directional Finder
will be greatly greatly greatly appreciated!!
Again, thank you very much in advance!!

I am in the process of building one this week. Should have it done
by monday and will take it to Dayton for display at the QRP ARCI
Hospitality suite along with a couple of other rigs that I've put
together. It is super quality both in parts and assembly manual.
I think as good as Heathkit was, but that's just my opinion and I
have invested considerable money and time in Heath since 1958. :-)

JB-

It sounds as if your computer was using a "hardware handshaking" routine.
You may only need to disable the handshake requirements at the computer end
of the link. I assume the three wires are send, receive and signal ground.
It might be as simple as connecting RTS to CTS.

There is no reason to panic. That labelling is on the cable so that it
does not have to be run in conduit in commercial installations. The NEC
allows low voltage wiring to be run outside of conduit, so they mark the
cable with a low voltage warning to make the electrical inspectors happy.
In fact, the voltage breakdown is about 8,000 volts, just like RG-8, assuming
there are no vampire tap holes in the cable of course. If the cable is
used, and full of tap holes, all bets are off.

About measuring more than 1kw at vhf with amodel 43, One simple solution is to build a directional coupler with the coupled value at about 40 dB. this method would require two dummy loads, one that would handle about 2.5-3 kw for saftey sake, and one that would handle 50 watts cw. Accuracy would not be great, but if you haven't had your 43 cal'd in the last six months to a laboratory standard, it's worse than about 10% anyway. Reverse the coupler to measure reflected power.

Hope this helps,
Joe Freeman

I'm not familar with your scope, bu thte majority of the time, the HV transformer only puts out about 300VAC. A voltage multipler/rectifer circuit does the rest. Usually, the primary of the transformer is fed with either line voltage, or for better filtering of line noise in the Z-axis, 12-25Vdc oscillated into a square or sine wave.
You May try taking an RMS voltmeter to the primary side of the xfmr to see where you need to start from.

I bought the TI C26 DSK last fall. I suggest you look at ftp orst.edu
(don't remember the exact address) or email forrerj@FRL.orst.edu for
his (johann Forrer) port of the W9GR DSP noise reducer/notch to this
unit. Look also for some other dsp modems; some of them with
a [well justified] price attached.

Does it meet my expectations?

Yah. Comes with RCA phono jacks in and out; 16-bit I think a/d and d/a
conv, sample up to 30 or 50 khz; lotsa demo software at ti.com
via ftp or a couple of other sites (one in Australia).

Bought a book - PC-DSP. Best 30 bucks I've spent in a while - it's
been superceded I think, probably even better - disks with programs
etc to design FIR, IIR and other goodies. Makes coefficients that
can be loaded into the DSK via it's D9 RS232 port. [I forgot to
mention that, didn't I...]

Then again, I'm just a learner. Check Arrow, other TI distribs. They
were short of stock a few months back. Great bargain.

There's a rumored C51 versio, but it keeps getting delayed.

Cheers / Mark

Reason for the "50V max" has more to do with National Electrical Code rules
than what the cable would be able to take. Apparently, the NEC rules are
looser with voltages below 50V, being used for "signal" purposes and not
for power deliverly. So, the manufacturer just marks it "50V max" to
avoid the extra grief of getting approval to handle higher voltages.
Ethernet is intended to be strung thru building ceilings and walls, and
would fall under NEC rules for safety and such.

Ethernet cable should be able to handle anything that foam RG8U can, or
pretty close.

The book "Transmitter Hunting: Radio Direction Finding Simplified" By Joe Moell K0OV and Tom Curlee, WB6UZZ (TAB books ISBN 0-8306-2701-4) has a large section on this topic. They talk extensivly about the Roanoake Doppler which is supposed to be pretty good for the money. A second source is of course the ARRL handbook (No ham should be without one).

Good Luck

981. Re: What can cause chirp in homebrew CW transmitter?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-22 16:14:52 UTC
From: ka7oei@uugate.wa7slg.ampr.ORG
Message-ID: <72768@uugate.wa7slg.ampr.org>
Source record: 117924

The cause of chirp in an xtal-controlled transmitter (or any crystal or most any oscillator, for that matter) can be traced to just a few things. 1) Component heating 2) Poor Voltage regulation 3) Poor load isolation 4) Temperature coefficients of other components.

I would guess that in the case of the 6L6 transmitter it is likely a combintation of the first two. Too much crystal drive will heat the quartz element and cause a chirp. Slight adjustment of some of the tuned elements or feedback components around the xtal may help. I would guess that the 6L6 transmitter used an ECO (an electron-coupled oscillator - Too bad there isn't a solid-state equivalent:-( ) so that isn't likely to be a problem if the design is reasonable. So, the next most likely thing is poor regulation of plate and bias supplies. See if the power supply "droop" "follows" the chirp. You may also want to check the "stiffness" of some of the bias supplies. Overdrive could not only result in crystal heating, but in overdrive of the tube and making a bias supply being dragged around from changes in grid current.

I'll bet your power supply is wandering around...

As far as load isolation, there's not much that can be done about that with a single-tube-element transmitter. Also, that sort of problem generally doesn't cause "chirp" per se, but rather your frequency would vary slightly with tuning, antenna swinging, etc. The component temperature coefficient problem (not to be confused with component heating) is also a long-term stability problem. That is, over the course of a 10's of seconds or longer the frequency would move around...

As far as power supply regulation, you may consider the normal tricks to improve dynamic regulation (i.e. a heftier "bleeder" resistor, a more substantial power transformer (if it's under-rated under load, etc.) a choke-input (a henry or 3 would help...) etc...)

Anyway, that TX sounds neat. There's something fun about operating an open-breadboard single-tube TX on the bands today... Just keep your hands (and those of others) clear:-)

983. 40 meter CW transceiver project?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-22 17:22:14 UTC
From: mmarmor@kuhub.cc.ukans.edu
Message-ID: <1994Apr22.122214.62719@kuhub.cc.ukans.edu>
Source record: 118016

Hello,
I am interested in building my first HF transceiver and would appreciate some comments from the net that might make the project more successful (or at least less frustrating).

I would like to build a simple CW transceiver for 40 meters (or possibly 30 meters) and have been looking through the 1994 ARRL handbook at some basic designs.

Since this is my first experience building HF equipment I want to give my self the best possible chance of success by picking a well known and easily built design.

Can anyone recommend a good "builder in training" 40 meter CW transceiver design? Will I be unhappy with the performance of this type of no frills rig? (It won't be any fun if I can't make a few contacts using it!)

All of the simple transceivers in the Handbook have QRP power levels between 1 and 5 watts RF output. I assume that higher power levels would require either more complex circuitry or more expensive parts. I would prefer to have a transceiver in the 25-50 watt range. Should I build a simple QRP transceiver and then try my hand a building a simple PA, or are there any uncomplicated (i.e. easily built, readily available parts, etc.) transceiver plans I have yet to see that feature power >5 watts?

I am not concerned with portability, just ease of building and useable RX and TX performance. I have access to basic electrical engineering test equipment here at the University as well as all back issues of QST.

I will be attending the Dayton Hamvention next week, does anybody know if there will be any seminars, meetings or booths that I might find helpful for my project?

I would appreciate any help you may be able to give, especially referrals to a well tested project that will fit my needs.

Source record: 118017

The problem is that the BIOS serial routines are expecting hardware handshaking. Quoting from my BIOS manual:

Int 14H XMIT
Transmits a data byte on the serial port specified by the DX register. The function enables REQUEST-TO-SEND and DATA-TERMINAL-READY signals, and then waits on the DATA-SET-READY, CLEAR-TO-SEND, and REGISTER-EMPTY signals...

You need to tie RTS to CTS and DTR to DSR. That should fix the problem.

I can only address what little experience I've had--starting with QRP. Try a simple design using a crystal for the frequency generation, rather than a VFO (to keep it simple). Shoot for 1-2 watts output. Once you're happy with that (and you will make contacts with it), you might try converting the oscillator to a VXO nd adding some more power with a PA up to say, 3-5 watts. I've taken this approach and been quite surprised with the contacts I've made, especially on 30 and 40 meters.

Let me know how you fare!

Message-ID: <1994Apr25.135359.577@arrl.org>
Source record: 117940

If you have plenty of time but no $$$, it is possible to substitute brass or nickel plated brass tuning screws in place of the expensive trimmer capacitors. You can either solder brass nuts or tap the enclosure to hold them in place. Another nut can be used to lock them into place. They don't have much tuning range at 2 meters, but will work if you carefully adjust the number of helix turns.

You could probably sell the "reject" filters at a hamfest to people who want to optimize their VHF reception at other frequencies :-).

: I have since found that Electrosonic carries them....at $20 EACH (Yeowch!).
: At this point, I am looking at Johnson air variables
: as a possible substitute.
: Even they are about $10 each.

995. PSK Modem

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-25 18:41:24 UTC
From: parnell_j@kosmos.wcc.govt.nz
Message-ID: <1994Apr25.184124.1@kosmos.wcc.govt.nz>
Source record: 117930

I would like to revisit the thread on how to do PSK demodulation that was running on this newsgroup a month ago.

EXAR XR-2123 is a PSK modulator/demodulator IC which was designed for Bell Standards 201, 212A or CCITT Standard V.22 (1200 Baud), or V.26 (2400 Baud) modems. The information in the EXAR data book about this IC explains in detail how the demodulation is achieved. Both carrier and data recovery are well explained. In addition, a typical modem circuit using the XR-2123 and other ancillary EXAR ICs is given.

Anyone wanting to learn how PSK demodulation is carried out would find the EXAR databook of great value.

Motorola make a pair of ICs, the MC 6172 and MC 6173 which also modulate and demodulate PSK signals. Application Note AN 870 covers the use of these ICs and presumably describes their operation but as I have not seen a copy of the note, I cannot comment further.

These days of course, modem speeds for most purposes are very much higher than 2400 Baud and the signal modulation/demodulation is achieved by digital signal processing. The EXAR and Motorola ICs described above are therefore effectively obsolete.

I wish to make a 2400 Baud modem card which will fit inside the my TNC-2 work-alike Packet Controller and connect to its expansion header. This will allow me to use the V.26 protocol port instead of the 1200 Baud FSK port on the local bulletin board.

Why is there a V.26 port you ask? Well, a number of commercial modems of this protocol became available, were snapped up by the local hams, adapted for packet radio use and put into service.

Question 1: Are the EXAR XR-2123 or Motolola MC 6172 and MC 6173 ICs available now from any source. If so, can someone please advise the source and cost on a one-off basis. They are unobtainable in this part of the world.

Question 2: Is there a DSP design (in either kitset or constructional information plus software form) available for me to build. If so, I would like to know the source and cost.

996. HELP! Recomend signal processing book

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-25 21:01:44 UTC
From: heiss@ualr.edu
Message-ID: <1994Apr25.150144.1@eivax.ualr.edu>
Source record: 117937

Hello all:
I have recently been subjected to a torturous course in signal
processing. This was in large part due to the miserable text book (
"Analog & Digital Signal Processing", H. Baher, John Wiley & Sons, New York
.) used for this course. The book is riddled with errors, ommisions and
missplaced references. Those of us who have used the book can not
understand how it went to press.
I would really like to understand signal processing but need some
help locating some books that are clear and practical, with the emphasis on
practical. I would like to be able to build both analog and digital filters
as well as write signal processing software. I need a book with lots of
"complete" examples.

Thank You

>personal style, and that is refreshing.
>Now, I'll call him and see if I can't talk him to selling a 900MHz
>data radio kit....

Now that would be worth having.

My experience with Ramsey kits has been spotty. The stepping motor driver worked fine. The 20MHz FM receiver was shipped with a few parts incorrect and one misdrilled hole on the board, but worked after Ramsey sent me the right parts. The 1GHz motion detector won't even oscillate. (I need to send that one in for repair; I don't have microwave test gear).

Chaney Electronics also makes kits, and some of them are sold at Halted Electronics (Lawerence & Central, Santa Clara, CA). I assembled their "ROAMR robot" kit, which works OK, but the mechanical design is really tacky (the wheels are knobs with rubber bands running around the outside) and it doesn't do much for something that has three ICs, two relays, and about forty discrete components. Also, a few holes in the board were not drilled out.

I appreciate that these guys are trying, but the Q/A still lacks something.

1002. Pinouts for UGN 3501U device?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-26 08:28:08 UTC
From: cwilliam@helium.Gas.UUG.Arizona.EDU
Message-ID: <2pijao$rlu@auggie.CCIT.Arizona.EDU>
Source record: 117935

In response to an earlier post about measuring EMF, someone kindly
suggested a Sprague (now Electro MicroSystems ?) UGN 3501U,
a magnetic sensor. I now have the device but don't have any info
about what to connect where. It apparently takes an 8-16 v. DC supply
and produces <1 mv out depending on the magnetic field. It is
a square about 1/4 inch wide w/ three pins. On one side it says
UGN 3501U 340 and the other side has a small depressed circle.

Could someone look this up for me? (It took a while to order & I hate
to accidentally destroy it.)

Thanks,

C. Williams

From: bruce@Think.COM
Message-ID: <2pjrfpINN48r@early-bird.think.com>
Source record: 117948

There is no usenet newsgroup devoted to QRP, but there is an Internet mailing list (which I administrate) devoted to the topic. To subscribe, send mail to majordomo@think.com containing the line

subscribe qrp

The list is also available in daily digest form (the volume of the list is pretty heavy); if you would rather receive that, do

subscribe qrp-digest

That being said, there is probably plenty of QRP interest to support a usenet newsgroup rec.radio.amateur.qrp. QRP is a rapidly growing and enthusiastic segment of the hobby. We routinely have 10-25 messages/day on the mailing list among the ~250 subscribers we have. Chuck (K5FO) and I started it as a mailing list a little over a year ago not knowing how much interest there would be, and preferring the intimacy and better S/N ratio generally had on mailing lists compared to newsgroups. If someone wants to drive the process of forming a newsgroup, I certainly wouldn't object, but I don't have the time to do it myself.

There's the 900MHz spread-spectrum band, where unlicenced low-power
operation is permitted. If you used a really low data rate, you might be
able to get a few miles of range. Alan Larson at SRI has done some work
with commercial units for this band.

1009. QST "Compact Loop Antenna" Suggestion

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-27 14:17:56 UTC
From: jcbach@kocrsv01.delcoelect.com
Message-ID: <1994Apr27.141756.7987@kocrsv01.delcoelect.com>
Source record: 117944
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

Regarding the article in this months' (May 1994) edition of QST titled
"You Can Build: A Compact Loop Antenna For 30 Thru 12 Meters" . . .

The reviewer mentioned that as he moves the motor forward/backward to "tune"
the antenna (he has a DC motor driving an air variable capacitor) the system
overshoots, "but it didn't take much practice to tune the antenna to nearly 1:1"

Looking at the motor control circuit, Figure 5 on page 36, it seems obvious what
a simple solution is . . . motor breaking. The way the circuit is currently
designed you either apply +V to go forward or -V to go backwards, but when
both buttons are released the motor terminals are open-circuited; thus the only
"force" to stop the motor is the mechanical friction (drag) in the system.

A quicker "stop" can be had by changing the circuit such that when both buttons
are released a "short" is placed across the motor terminals, and thus the back-EMF
will stop the motor. This is how many power door-locks (yes, they are motors NOT
solenoids!) and power windows are wired in cars . . .

To change Figure 5, replace the DPDT switches (one "throw" of which are "no
connects") to SPDT, and rewire as shown (crudely) below:

```
GND----O\
\ "Fwd"
\O------------ Motor+

V+----@---------O
|
|
| GND----O\
| \ "Rev"
| \O------------ Motor-
|
----------O
```

Thus, when both buttons are released, the motor windings are "Shorted", and thus
max drag on the system. When the "Fwd" button is pushed V+ is applied to the
motor, when "Rev" button is pushed -V+ is applied to the motor, and IF you are
so inclined to push BOTH buttons at the same time, then V+ is applied to both
terminals and once again a "short" is applied to the motor.

Please use the "Break before make" type of switches so you are not spiking current
thru the switches at each activation :-)

Hope this helps . . .!

1. Does anyone have any design information for such a product?

2. There are several commercial ICs available. Any suggestions on which ones to use?

To answer this question, see radio electronics experimenters
handbook (magazine construction compilation). It had several fm transmitters in
it, although none digitally controlled if I remember. Several stereo though.

3. Has anyone taken the guts of a cordless phone and modified it for this? It would seem that
this would be the most "elegant & inexpensive solution".

I have been inside several cordless phones, all 49mhz type.
They all were xtal controlled, & the one I have now is an
at&t and puts out a tremendous whine along with the
signal on a scanner (around 6khz I estimate), this is filtered out by
the phone base unit, I assume its for control or security to keep the base
from being triggered by remote control toys on 49mhz also.

My $.02

Ed

Larry,

Theres not much on the book shelves that isnt pretty well steeped in
Math.

Be ready to spend some bucks.

Here is one that you might look into:

"First Principles of Discrete Systems and Digital Signal Processing"
by Robert D. Strum and Donald E. Kirk
Addison-Wesley Publishing Co. ISBN 0-201-09518-1

It has lots of math but if you are into that kind of thing, it might
be ok.

Anybody else have any suggestions?

Henry

Dear newsreaders,

This is my idea for a 'liquid' state radio, which I intend to make for my electronics assignment (worth 50% of years mark). I would like your thoughts on it, and if possible, give me information on how to build the capacitor, the inductor, the antenna, the detector and the battery. It's a crystal set, but it is indeed a very special one (liquid state):

Detector

I intend to make a 'Wollaston' wire detector. This involves silver coating 'Wollaston' wire with silver, and then dipping it into some nitrate solution and this apparently has rectifying properties! Does anyone know what Wollaston wire is, or has information on liquid state detectors?

Capacitor

I'll try and do a metal-plates-in-transformer-oil job. Does anyone know what goes into building one of these? ie. is it easy? To change the capacitance (to tune), you would take out some liquid or put in more.

Inductor

I'm thinking of winding about 500 turns of wire on a ferrite core.

Battery

This is a beer and copper coins job. However, I can only get about 1.2V out of 8 copper coins with beer soaked cloth in between. How can I get about 3V out of it so I can drive a pair of headphones?

Antenna

I think I'll either get a old external TV aerial (but that's for FM, isn't it?), or get lots of wire and run it around trees at the university. Can someone please recommend wire for this?

And that's basically my liquid-state radio.

Why build such a radio, you might ask? Well, the rest of the class will probably be building some hi-tech solid state radio, and I think it'll be a real novelty to build a liquid-state radio.

Thanks, in advance,

Kenneth Teo

Source record: 117955
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Hi, I'm having some difficulty working with my ATV setup. I've got the AEA VSB70, and I've built the 8-element quagi antenna from the ARRL book. I don't seem to be getting the kind of performance I think I should, it's pretty fuzzy at only three miles away with a direct line of sight. I need some advice on how to go about tuning the antenna. What kind of test equipment do people use? I've gone to both my local ham stores and they've told me they don't have any SWR meters that will work up to 500MHz with under one watt of power. With no SWR or power meter, it's pretty hard to tune the antenna. Are there any other methods? Can anyone recommend a good SWR meter? Or should I give up on making my own antenna and just buy one (what the ham store recommended)? Anyone else with experience using the 8-element quagi for ATV? What kind of performance should I expect if it's working properly?

Also, I'm thinking about getting an amp; probably the SAU-4 brick. Does anyone have plans for putting an amp together with this module? Or any recommendations for a better solution?

Finally, are there any ATV resources on the Internet, eg. mailing list, ftp site, etc.?

Thanks in advance... <Jeff ve3 kyh

I'm certainly not a regulatory expert, but my experience is that
very low frequencies tend to handle obstructions the best. The
Navy uses them to communicate with submarines. I've actually
heard VLF signals through our solid metal screen room walls.
(it isn't designed to stop such low frequencies). But, generating
strong signals generally requires large antennas and high data
rates are usually considered impossible. Noise at VLF can also
be a big problem. But, if you want signals to go through water,
concrete, and steel, consider frequencies below 30 kHz.

I did call Rick Campbell at his home in MI. Nice guy. Told me that they were not able to produce anymore boards through their current supplier. However, he was actively looking for another source for the boards and that there were two potentials on line.

Rick also mentioned that he had talked to Wes Hayward (w7zoi?)
about some enhancements to Rick's design. I'm not sure what they were though.

Be on the lookout for updates and new designs in upcoming QSTs.

1020. Screen voltage on 4CX250B's: One more question...

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-28 19:03:37 UTC
From: dgf@netcom.com
Message-ID: <dgfCozGy2.7Gy@netcom.com>
Source record: 117967

Thank you for the comments on my last posting about 4CX250B screen voltage supplies. From this I gathered that a shunt regulator was good, and a series regulator was bad (due to possible negative screen current). On this advice, I picked up some 100V 50W zeners, and I already have some 27V 10W zeners. I'll arrange these into a shunt regulator, but here's the questions:

(1) To have choice of several screen voltages, can I start w/ say 300V shunt regulated, then use some of the 27V zeners reverse biased in series to cut the voltage if desired, or should I arrange taps in the shunt zener string itself (i.e., two 100V and four 27V zeners in the shunt regulator)?

(2) For two tubes, should I feed them from a common screen voltage supply, or give each it's own separate zener shunt regulator?

(3) I was told several times that the screens can be killed due to excessive screen current (ask me - I nuked an 8874 grid in my earlier days - $$!$$!!!); would a low-current fuse on each screen DC feed work (say 1/32A per tube) or should I try for a solid state regulator?

Or should I give up on the whole mess and go for grounded grid ;-)

1022. Vertical yagi mounting

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-28 20:55:12 UTC
From: phb@syseng1.melpar.esys.com
Message-ID: <phb.767566512@melpar>
Source record: 117966

In a recent on-the-air discussion, I pointed out the error of mounting a two-meter yagi in the vertically-polarized position while using a metal mast (assuming that the antenna mounts from the center of the boom and not at one end, the latter being common for 3- and 4-element yagis).

One of the on-the-air participants, admittedly a new ham, became very defensive and said that he used a Cushcraft A147-11 vertically polarized on a metal mast, and his antenna "had directivity."

So, I have a couple of questions based on my assumptions as follows:

1) I assumed that a metal mast, being in effect a non-resonant "extra" element suddenly stuck in the middle of a parasitic array, would detune the antenna and probably throw the radiation pattern off by creating either more than one lobe or skewing the main lobe above or below the plane of the array by some noticeable amount. Is this assumption anywhere close to correct?

2) I once heard two hams testing a A147-11 which ham A had just installed, and he was trying to figure out why station B was stronger when the antenna was about 30 degrees off-azimuth from Station B's known location (the antenna was vertical, BTW, and the two stations were about 60 miles apart). Ham A was using a - you guessed it - metal mast. Does this result sound reasonable?

3) Has anyone out there ever purposely installed a yagi array vertically using a metal mast and tried to measure the effects (VSWR, azimuthal pattern accuracy, etc.)? I have a A148-10S which is currently mounted horizontally, and have been toying with rotating it into the vertical plane and trying to measure the effects, but maybe someone else has tried it out of scientific curiosity.....

Hi Jeff,
I've been using quagis on ATV and other stuff for several years now with
good results. I suspect that the bandwidth of a quagi, though better than
a straight yagi, is still a bit narrow for a full atv signal, but it
seems to
work. I get a low swr for about 3-4 mhz bandwidth typically.

I've typically cut mine for the video carrier frequency or a little
higher,
tuned them using a radio shack VHF/UHF wattmeter/SWR bridge and my ht
and then tweaked them with the video signal. The RS meter has a 15 and 60
watt scales, isn't terribly accurate, but it can tell you when you are
reducing
the reflected power and give you a feeling for how good or bad the
antenna is.
Do I trust the SWR measurement, not a bit. But that doesn't mean it isn't
useful.
(cheap too, $30 currently) I usually use my HT to take swr measurements at
1 mhz intervals and trim the driven element and if necessary the
reflector to
get the response I want. SWR with the video signal will be higher than
with a
carrier because parts of the signal (sound carrier, etc) will be up the
swr curve
a bit and you have a lower sideband (well,you don't) that is out of the
passband of
the beam. Haven't toasted any finals yet with this rough and ready

method.

I took the data in the handbook for the 440 and 432 quagis, developed a simple
pascal program to interpolate them to get data for other frequencies, and use
that to calculate antennas for need (421 for repeater reception, 439 for the
input or simplex, 435 for Oscar work, etc)

Currently we are using a home brewed quagi (built on a 2x4 boom - usually I use
a 1x2) for our ATV repeaters transmit antenna. I use a couple for field shots, other
stations in the area use them for both transmitting and receiving. So they do work.
Ranges are in the 10-20 mile range for P4-P5 from the repeater running 10 watts
at good elevation. Talking back to the repeater range with a watt runs in the 5 mile
plus range with good results. Sounds like there is something awry in your system at
one end or another - or it could just be terrain.

Be interested in hearing about your experiences - here or email.

According to my simplex pal across town, his Cushcraft yagi manual actually says to mount them that way or at least it has pictures of the yagi vertically mounted with the mast sticking up only a couple of inches above the boom. Other weirdness in the Cushcraft manual is a picture showing the coax routed across the top of the insulated elements. Maybe the marketing folks at Cushcraft took all the pictures. I've seen their collinear arrays upside down in magazine ads.

>1) I assumed that a metal mast, being in effect a non-resonant

I've heard that if you have to do it, then stick the mast up until its even with the top elements so as not to destroy the symmetry so much. I've modeled both ways with the MN antenna program and it screws up the pattern pretty good but mostly at the expense of forward gain. My real experience is not so easily measured but I know a 7 element 2 meter yagi improved for both vertically and horizontally polarized signals after I mounted it horizontal. Previously I had tried both metal and wood masts but still ran the coax down the wood mast with the yagi vertical. The coax will also become an unbalanced and unwanted element this way.
My KLM 2M14C circular yagi manual says to mount the thing on a non-conductive mast or boom and run the coax off the back end. It works okay this way. I found a telescoping fiberglass broom or window squeegee pole at the hardware store that is pretty strong and about 6 feet long when collapsed. You only need to get about 4 feet away from metal but 6 or 7 feet is better at 2 meters.

I don't know what others think about this but the only place
for a metal mast on a vertically polarized yagi is on the end
where it may act as a reflector.
Better yet, buy two yagis and cophase them on a horizontal
boom.

Source record: 117959

I'm not sure what the circuit looks like inside the 612. I'll pull the schematics tommorow and look. Most of the HP sig gens I work with(older ones anyway)
work with a tuned cavity oscillator. Newer ones are based on the Yig tuned oscillator which is tuned by means of a low intensity magnetic field around the Yig mass.

I have never had a problem personnally with one of the HP tuned cavity type oscillators, but I have heard of them failing sometimes. Most of the Hp sig gens that used tuned cavity oscillators (the 8640 in particular) used the Tuned cavity to generate the highest band of frequencies that would be output. The tuned cavity can be a harmonic rich environment and all you had to do was filter the output of the cavity to the right band of frequencies. So long as you had a signal across one full band (usually the highest band), the oscillator was okay. If you lost other bands, it was normally the filter circuit or the cams in the switch that selected the proper filter network.

If we still have the 612 service manual, I should know more about it tommorrow.

>Or should I give up on the whole mess and go for grounded grid ;-)

My input: on the smaller tetrodes like the 4CX250B, grounded grid does not absolve you from supplying screen voltage. Many, many times have the EIMAC guys written that you don't tie grid and screen together in cathode-driven with small tetrodes, because that darn screen will still draw current and melt down.

You can (of course) do it with "higher perveance" tubes like 4-400A, 4-1000A, etc. But, unfortunately, you're still stuck with the screen supply!

A couple of followup comment from the original poster:

> One of the on-the-air participants, admittedly a new ham,
>became very defensive and said that he used a Cushcraft
>A147-11 vertically polarized on a metal mast, and his antenna
>"had directivity."

NOTE: My on-the-air comments did not suggest the antenna
had "no directivity", only a screwed-up pattern, but the
"defensive" ham took it that way.....

>pattern off by creating either more than one lobe or skewing
>the main lobe above or below the plane of the array by some

Poor choice of words; "above or below the plane of the array"
implies the antenna is horizontal when it isn't; what I mean
here is that the major lobe no longer points in the same direction
the antenna is pointed because of the deleterious effect of the
metal mast, which is now parallel to the parasitic directors and
has a detuning effect.

1029. Newbie code Practice receiver -- feasible?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-29 14:25:37 UTC
From: vinod@watson.ibm.com
Message-ID: <2pr5d1$l20@watnews1.watson.ibm.com>
Source record: 117880

I took my no-code tech exam couple of weeks back, and
am now learning code from tapes while waiting for the
licence. I would like to get up to 13wpm so that
I can upgrade to general when I take the exams.

I would like to have a code-practice reciever to
get the code practice sessions from W1AW and also
perhaps to listen to other conversations going on
in the various bands. Since I don't know what
kind of radio I would eventually want, I don't really
want to buy a traceiver yet. Most of the cheaper
commerically availabe receivers don't receive CW and SSB.
So, I am thinking of building
a simple receiver, either as a project or
preferrably from a kit. I will basically have only a
multi-meter available, and I don't have any experience
with building RF circuits.

Given the above,
1. Can somebody recommend a good, inexpensive kit ? I just
got the catalog from ten-tec yesterday, they have a a kit
for $39. This is a new business for them, so I don't expect
anybody has built this yet, but if they have, I would like
to hear about it..

2. Is this kind of project feasible, or am I better off looking
for a used receiver? (Well, I intend to look at the local hamfests
anyway, I was just wondering about how feasible the task is in
general, given that I don't have much test equipment).

Thanks for any comments, advice, references etc. in advance.

>scientific curiosity.....
>
>

I'm posting this because e-mail to you bounced.

When I mounted my Cushcraft 15 element 2M yagi on the center of my mast in vertical polarization, I arranged it so the person at the top of the tower could adjust the axial rotation (of the boom) while I monitored SWR at the bottom of the tower (thru about 60' of RG213). The bottom line is the SWR went way up (over 2:1) within 10 degrees of true vertical, and we settled on about 20 degrees off vertical (favoring the orientation that improved drainage away from the balun box) which minimized SWR (not the absolute minimum, but I accepted a 1.3:1 as OK).

In this situation, I get about 10 dB gain *over* a diamond 10 foot gain vertical which is mounted about 10 feet higher on the tower (at the very top of the mast). Everything is operating about as expected (the diamond has about 6-7 dB of gain on it's own, and the beam appears to have about 10 dB more gain in it's favored direction).

I did not measure "directivity" or any other factor in the straight-vertical orientation, because the higher SWR was disabling my brick at the bottom of the tower.

I hope this helps.

1031. FTP site with 16,000 CIRCUIT references

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-04-29 16:37:16 UTC
From: psawatzk@uoguelph.ca
Message-ID: <2prd3s$o46@nermal.cs.uoguelph.ca>
Source record: 117884

Thought this group would be a good place to make it known that we have a database of about 16,000 bibliographic references (from over 350 magazines/journals) of articles/papers containing practical electronic circuit designs.
Just ftp gaitlab1.uwaterloo.ca
Directory /pub/circuits/demo contains a small demo.
Directory /pub/circuits/main has the big one (~3Mbytes before unzipping, ~9Mbyte after)
[be sure to give a bin command before getting the binary files]
The database has a front end for searches on title, device numbers (eg 741, 2N3904, MC1496, etc.), and circuit descriptions. The individual files are also dBASE-compatible, so if you don't like the front end you can use many other utilities to extract data.
Subject matter covers just about every field, including RF, audio, computers, interfacing, DSP, etc.
Copyrights are honored (registered with CCC - the Copyright Clearance Center), so if anyone needs hard copy of articles from those periodicals that qualify, they can get them. We're hoping to update annually or semi-annually.
Any comments and suggestions are welcome.

: heard VLF signals through our solid metal screen room walls.
: (it isn't designed to stop such low frequencies). But, generating
: strong signals generally requires large antennas and high data
: rates are usually considered impossible. Noise at VLF can also
: be a big problem. But, if you want signals to go through water,
: concrete, and steel, consider frequencies below 30 kHz.

Maybe I can share my past experience on designing 900MHz cordless phone.
It is true that frquencies as high as 900MHz has no advantage for
penetrating concrete. The $100 worth 900MHz cordless phone has coverage
similar to a $30 46-49MHz counterpart. Also at high frequencies,
problems associate with multipath fading become serious.

However, it is a trend that communication devices are getting higher and
higher in operating frequencies. That may be due to the following
points:

1. There is virtually no room at the lower end of the spectrum. On the
other hands, higher the frequency, wider the bandwidth will be.

2. Consumer product must have a small size. Low frequencies require
huge antennae.

3. With spread spectrum technology, the problem of multipath can be more
or less improved.

I've installed a Yagi vertically mounted on a metal mast and I experienced detuning. I couldn't tell you how the radiation pattern was affected since at the time I had no way of determining that - but since I was operating on 2m, I installed a horizontal counterbalanced boom and remounted the antenna a few feet away from the mast. That seemed to help a good deal, although there was still a little bit of detuning remaining.

Word from the mailing list qrp@think.com has it that Rick is no longer
making the boards, and is looking for someone to take over.

About time; poor guy has probably been swamped, and several stories of
long waits, SASE's not returned (3 in my case!).

My wish would be for a supply of matched inductors/capacitors for those IF
diplexers in the R2 -- I've done without them, and it works well, but
would be nice to do it perfectly!

Maybe some kit supplier could provide 1) boards 2) partial kit, including
the precision stuff and the inductors/caps that have to be matched, or 3)
complete kits.

Any takers?

: guys written that you don't tie grid and screen together in cathode-driven with
: small tetrodes, because that darn screen will still draw current and melt down.

: You can (of course) do it with "higher perveance" tubes like 4-400A, 4-1000A,
: etc. But, unfortunately, you're still stuck with the screen supply!

--
I must have missed the original post for this. I understand that it is best to
provide both screen voltage and grid bias voltages for a cathode driven 4CX250
tube (grounded grid). I'm not sure what the ideal voltages are, but would
guess that at 2kv plate voltage, you might want something about -100 grid and
+250 screen. The data sheets would tell you for sure.

Paul: This is an excellent problem for testing with the newer versions of MIninec or NEC on the market. I have done a good bit of modeling of stacked and interlaced 10/15/20 meter yagis and can confirm that a 20 meter element in the middle of a 15 meter yagi is bad news in that it can cost you 1 to 1.5 dB of gain, change the input Z some and cause most anything to happen to the front to back. I have not tried a random length mast but I would expect the same sort of results. 73 Bill

1038. Periodic Announcement - ARRL Email Information Server (info@arrl.org)

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-02 14:38:55 UTC
From: mtracy@arrl.org
Message-ID: <89680@mt.arrl.org>
Source record: 117874
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew,rec.radio.info

Periodic Announcement - ARRL Email Information Server (info@arrl.org)

The services that the ARRL provides via the internet include the
Email Information Server and the Technical Information Service.
The Information Server is an automated mail server that gives you
access to many of information files relating to various facets of
Amateur Radio. You can retrieve any or all of these files by
sending an email message to info@arrl.org here at ARRL HQ.
Each file you request is then mailed to you automatically.

To use it, mail messages to:

info@arrl.org

Each line of the message body should contain a command as shown below.
The subject of your message is not processed and may be omitted. You
may place as many commands in a message as you want. The files you
request will be sent to you in separate messages. Only ASCII text
files are supported.

Valid INFO commands:

reply <address> (may be needed - see below for explanation)
help
index
send FILENAME (example: send prospect.txt)
quit

In the above message example, "help" retrieves a brief set of
instructions for info, "index" retrieves a list of available files
and "send prospect.txt" retrieves a text file containing information
on becoming a radio amateur.

Note to users with FTP capability: All of these files are also
available by anonymous ftp to oak.oakland.edu in the
pub/hamradio/arrl/infoserver area. Retrieve the file index.txt
in the /league sub-directory for a complete listing of available
files.

If you want to retrieve several text files with one message, use a
separate line for each "send filename" request.

Your From: field or Reply-to: field in your header should contain a
valid Internet address, including full domain name. If your From:
field does not contain a valid Internet address, the answer will not
reach you. If this is the case, then use the reply command as shown

above. When needed, this command should always be the first command
in your message.

IMPORTANT: Please use the quit command in your message. This will
prevent processing errors from message signatures.

PLEASE NOTE!: This is an automated system not capable of handling
written requests. Any questions on the info-server or the content
of any of its files should be directed to mtracy@arrl.org.

ALSO NOTE!: Do *NOT* reply to messages sent from info@arrl.org - the
reply address is redirected to keep bounced messages from endlessly
looping. Write a new message to info@arrl.org instead.

The Technical Information Service gives League members on the
internet better access to the knowledgeable technical staff here
at ARRL HQ. Questions relating to Amateur Radio and related
technical topics are welcome. To use this service, send a normal
e-mail message to tis@arrl.org with your question spelled out in
plain english. For best service, be as specific as possible and
keep your line length in messages to a maximum of 80 characters.
Due to personnel limitations, priority will be given to questions
from League members.

Best Regards,

Michael Tracy, KC1SX, ARRL Technical Information Services Coordinator
(e-mail mtracy@arrl.org)

Sample of files available from INFO: (There are lots more!)

Note - If you are not yet an Amateur Radio operator retrieve the
file prospect (send prospect) for information on how to easily get
started in this fun hobby.

I bought a kit to do just this thing from a company in
Pennsylvania called Radio Adventures Corp. They have had an ad in the
back of CQ somewhere for a while. It only picks up W1AW on the 40m
band (other bands available) but has very minimalist filtering, so I
can occaisonally hear some English-language SW broadcaster that I can't
quite seem to comprehend (part of which may all be because my antenna
system is just a random wire about 15m long...). The receiver will
definitely pick up W1AW and was somewhat useful as my first kit, as I
got plenty of "oops - all those parts weren't supposed to go on that
side of the PC board, were they?" type of experience out of the way...

Kenneth, what kind of earphone/headphone are you using for this W1AW receiver? I built one for 20 meters and shelved it, because, in any of my "walkman" type headphones, or an old style earphone, the audio output is minimal. I wrote to the fellow, and he recommended Koss "ear-buds", but I'm not so sure I want to invest any more money in this. Also, it has no shielding and is very susceptible to local AM broadcast. I wish I had waited for Ten-Tec to produce their kit line.

Howard

I also bought one of those Radio Adventures kits but I found it
essentially useless. When I'd talked with the company before ordering,
I was assured, oh, no problem, you should be able to pick up W1AW with
a 10' piece of wire as an antenna, you're so close. (I live outside
Boston, seemingly not all _that_ far from Newington, CT.)

In fact, the kit will pick up W1AW but not so well that anyone I know
could possibly have the patience to try listening. Even with an
outside antenna, you can barely hear it. It's pitiful.

Now, in point of fact, W1AW is just not that strong a signal in many
places. With that same outside wire antenna, I can always find W1AW's
80m and 40m signals on my FT-990 and those signals are always fairly
easy to copy, but nonetheless, there is also quite frequently an annoying
amount of QRM and fading.

My advice is to not to waste your money on something cheap. You only
get what you pay for. If you're looking for some inexpensive code
practice, get the ARRL code practice tapes. They _really_ work and
they're really worth the money.

Don't expect to practice with the W1AW signals (depending on your
location) until you get a "real" radio.

I did a little modelling with NEC. I first constructed a rough 4 ele yagi
and got a resonable pattern. Then I added a long vertical pole roughly in the
center of the yagi. This really buggered the pattern. Ok so I did this at
Band II where I have a good idea of the size of things off the top of my
head, but it still applies to 2m. Here is my NEC input file.

```
CM vertical Yagi
CM
CM
CE
GW1,25,0.,0.,-.9,-.,0.,.9,.01,
GW2,25,.76,0.,-.76,.76,0.,.76,.01,
GW3,25,1.3,0.,-.6,1.3,0.,.6,.01,
GW4,10,1.9,0.,-.6,1.9,0.,.6,.01,
GW5,25,1.,0.,-2.65,1.,0.,.35,.03,

FR0,1,0,0,96.,0.,0.,
RP0,1,359,1010,90.,0.,0.,1.,0.,0.,
EN
```

So I guess the answer is don't use a metal pole with a vetical yagi.

Howdy --

I've been interested for a while in time and frequency measurement, and have been collecting bits and pieces of equipment.

At the Hamvention last weekend, I finally found my dream: a rubidium standard. It's a little Efraton thing (part number 100323-101 for what that's worth) and it seems to work.

But one problem is that it only has a single 10MHz output, and my other equipment all wants either 1MHz or 100kHz inputs. So, I need to design some divider and distribution stuff -- and I'm clueless about how to minimize phase shift and jitter, and how pure a sinewave output I need to shoot for (or will my other equipment be happy with squarewave input?).

To get to the point, I'd be interested in corresponding with anyone out there who's knowledgeable about frequency standard/measurement systems, so I can get this thing lashed up properly.

Thanks...

They tend to be in the picofarad range, but with very high breakdown voltages. They're pretty easy to rebuild too, since they are basically just Reynolds Wrap between sheets of glass. You can calculate the exact value of the capacitance with the formulae in the ITT Handbook (which will also give you the dielectric constant of glass), if you want to replace it, but it would be easier to rebuild it.

I'd like to gauge the interest among members of 10-10 International who
are on the Internet for a group, possibly called:

rec.radio.amateur.1010

The purpose of the group would be multiple:

1) to help disseminate information of general interest to 10-10 members
who have access to Internet.

2) to help 10-10 members set up skeds, nets and other communications events.

3) to help develop interest in not only 10-10 International but to maintain
interest in 10 meters in *spite* of the current lull in the band.

4) to help develop computer operating aids for 10-10 contests and
paperchasing.

5) to serve as one focal point for 10-10 members to discuss the organization,
contest rules, awards rules, etc.

6) other future purposes realted to Amateur Radio and 10-10.

****

I think that emailing me would probably be preferred to clogging up
a number of newsgroups with "me too!" kinds of mail.

If you are interested or have a *brief* thought on the subject, please
email:

wb9omc@harbor.ecn.purdue.edu

flames and/or mail bombs will be ignored, deleted, /dev/null'ed, etc. :-)

If interest seems positive enough, I will make some contacts with the
officers of 10-10 to find out in what ways, if at all, they would
like to make contact and maintain contact with such a newsgroup.

My father used a wooden pole to mount a vertical yagi, but I pointed
out "what about the coax running up the wooden pole to get the radio
connected to the antenna?". He figured that, yes, it will have some
effect, but the coax being smaller than a metal mast, would not be
as bad. Don't really know. Would it help if we used ferrite beads
on the coax spaced something like one every 1/6 th of a wavelength
(or some such smaller than 1/4 wavelength) to be nonresonant? Idea
is to "break" up the coax into many short pieces to RF on the outside,
so it looks like non-significant short pieces of wire. ?

1056. Screen Supply for 4cx250B

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-04 13:43:15 UTC
From: M.Willis@ee.SUrrey.ac.UK
Message-ID: <9405041443.aa05346@harad.ee.surrey.ac.uk>
Source record: 117896

It is important to get the screen supply right. It needs to be between 250 and 350V depending on class of operation, 330V is good for SSB. Grid needs to be -100 or more for cut off and about -50 during operation. Standing current in linear mode is 100mA. I know that is 200W dissipation at 2Kv on the anode but those are the specifications for a clean signal. The screen supply must be very stable and capable of sourcing or sinking 30mA. When I say stable I mean to a few 10s of mV with speech, not long term drift. It needs to be an active shunt regulator, definately not a string of zener diodes! There are some good designs in the VHF/UHF DX Book. If you are not interested in a clean signal and only want to run in calss C, set the screen at 250V with zeners, bias current to a few mA with the grid at -60V or so and you will get 400W from a single valve. It won't be linear but it wouldn't be in class C would it?

: good results. I suspect that the bandwidth of a quagi, though better than
: a straight yagi, is still a bit narrow for a full atv signal, but it
: seems to
: work. I get a low swr for about 3-4 mhz bandwidth typically.

True, if you try to optimize a yagi one element at a time, you do
tend to get a narrow bandwidth. But, it is possible to do much
better with very long yagis. The 1992 Eastern States Conference
has a design by Tom Kirby that has plenty of bandwidth for ATV,
even at 135 cm (I realize the band isn't big enough). From 220 to
226 MHz its gain is from 18.4 to 18.7 dBi, while the SWR is below
1.4 to 1. However, even on 70 cm, 25 elements on a 17 ft boom may
be a little too big for some applications. The 22 element K1FO
yagi for 432 also has a pretty wide bandwidth.

: scientific curiosity.....

Kent Britian measured a 2.2 wavelength 435 MHz DL6WU yagi
on his test range.

With the mast all the way through the yagi, the gain varied by
+1 to -10 dB.

With the mast half way through the yagi, the gain varied by +1
to -6 dB. There appear to be more spots to put the mast in
without degrading it too much, but this might be yagi specific.

He varied the spacing between the driven element and the mast.

The results appear in the 1993 AMSAT-NA proceedings (11th)

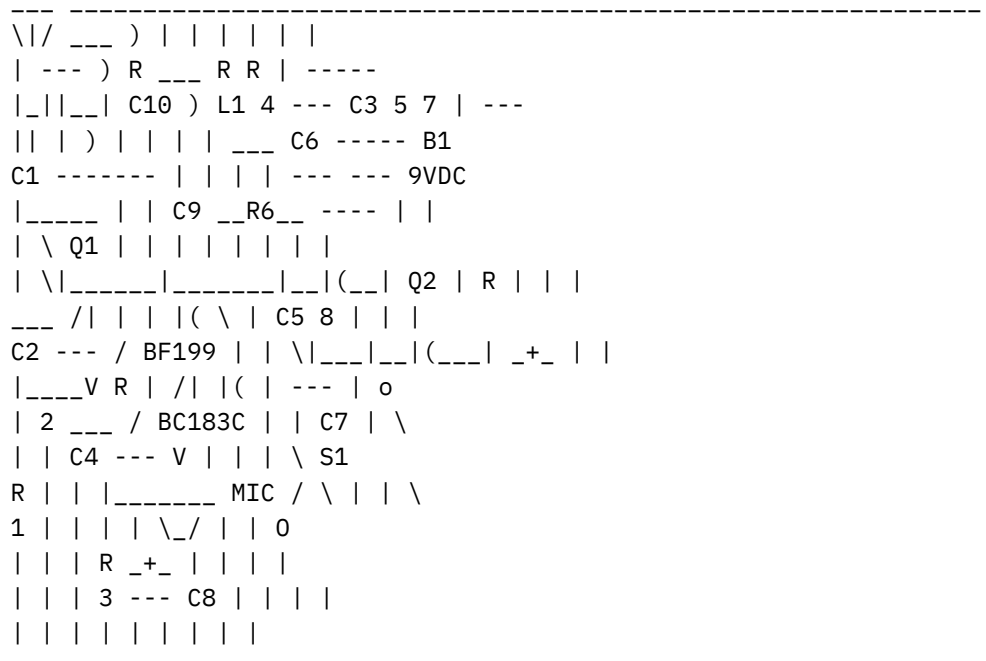
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics

This is the circuit for a simple FM wireless microphone, published in the 1990 Radio Electronics "Electronics Experimenters Handbook", pp. 155-157. It's simple and handy to have - pretty much the same as the "Mr. Microphone" they sell (or used to) at Radio Shack. Range of maybe 100 feet, on standard broadcast FM receivers.



R1 = 100 ohms C1 = 1.5 pf cer. disc Q1 = BF199, NTE 229,
R2, R4 = 10K ohms C2 = 100 pF, NPO ECG 229 or eq.
R3 = 1K ohms C3, C4 = 330 pF NPO Q2 = BC183C, NTE199
R5, R7 = 47K ohms C5, C9 = .1 uF NPO ECG 123AP or eq.
R8 = 4.7K ohms C6 = .001 uF NPO L1 = approx. 1 uH
M1 = electret mike C7 = 22 uF electrolytic S1 = SPST switch
B1 = 9V battery C8 = 6.8 uF electrolytic
C10 = 10 - 40 pF trimmer capacitor.

The coil L1 is so small that in the PC board version of this, it's just a coil etched on the board with traces. I think I breadboarded it with about four or five turns of bell wire around a pencil and that made about the right value. You tune the sucker with the adjustable cap C10. If I remember, the transistors are garden variety ones, though I think Q1 was reasonably high frequency. I was feeding in a signal other than an electret microphone.

This is neat to use with a cheapo FM walkman-type radio for cheap telemetry. (We were actually going to build a device to transmit strain gauge signals from someone's teeth over a whole day's time, and it was to be small enough to be relatively unnoticed INSIDE THEIR MOUTH the whole time. Never did get the O.K. to proceed with that one. Working for university research gets pretty strange sometimes.)

1062. Yagi detuning due to mast

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-04 17:58:07 UTC
From: phb@syseng1.melpar.esys.com
Message-ID: <phb.768074287@melpar>
Source record: 117900

This repost replaces "Vertical yagi mounting" and "Adjusting vertical polarization of yagi" posts.

POSTED REPLY:

of RG213). The bottom line is the SWR went way up (over 2:1) within 10 degrees of true vertical, and we settled on about 20 degrees off vertical (favoring the orientation that improved drainage away from the balun box) which minimized SWR (not the absolute minimum, but I accepted a 1.3:1 as OK).

COMMENT:

Thanks for the info. BTW, the reduction in gain at 20 degrees slant relative to vertical is about 0.5 dB; i.e., your yagi has about a half-dB less gain when you're "looking" at a vertically polarized signal than it would if it was exactly vertical. FYI, 45 degree slant linear polarization reduces the gain 3 dB for either vertically or horizontally-polarized signals.

POSTED REPLY:

I did not measure "directivity" or any other factor in the straight-vertical orientation, because the higher SWR was disabling my brick at the bottom of the tower.

COMMENT:

Well, it looks like no one really has; I feel an experiment coming on.....

POSTED REPLY:

I've installed a Yagi vertically mounted on a metal mast and I experienced detuning. I couldn't tell you how the radiation pattern was affected since at the time I had no way of determining that - but since I was operating on 2m, I installed a horizontal counterbalanced boom and remounted the antenna a few feet away from the mast. That seemed to help a good deal, although there was still a little bit of detuning remaining.

COMMENT:

An interesting variant on overcoming the problem. In both of the cases noted, the amateurs involved measured the VSWR and tried to find a way to reduce it, which is a good approach if pattern variation is ignored. I'll wager, however, that there are quite a few hams using transceivers WITHOUT any automatic VSWR shutdown

who are also using vertical yagis with metal masts and have NO IDEA that the VSWR is excessive. Probably won't hurt the rig, but for any significnt amount of coax they're probably wasting a lot of power as heat in the feedline.

I will probably set up an experiment with some locals and try to map out performance in terms of directive pattern skewing and VSWR as functions of slant angle. I'll repost when I have some data to report. Thanks for the replies!

The capacitance of a parallel plate capacitor of typical dimensions is:

C(farads) = 8.85*10^-12 * er * (N-1) * A(m^2) / S(m) where

C = capacitance if farads
er = dielectric constant of dielectric relative to free space.
Somewhere around 2.0 for glass as I recall.
N = number of plates, two for a basic capacitor
A = area of plates in meters squared
S = spacing between plates in meters

Source record: 117901

I am looking for data sheets on a TA7745P 3-phase commutator chip (18 pin dip i think) for driving a small servo motor.
Toshiba (who makes it) says they sold that division to industrial indexing who say they don't handle single component peices.

I know i can buy it from MCM electronics but they don't happen to have any data on the chip itself.

(i've seen a schematic that implies i wouldn't need to use any outboard driving transistors for this small servo motor i have. this sounds much simpler then using motorola's or National's driver chips which do seem to need external components.)

any info or directions to info would be appreciated.

thanks,

Jim:

Like most single op-amps, this one follows the norm. The pin out is as follows

1 balance
2 - input
3 + input
4 -v supply (or ground)
5 compensation
6 output
7 +v supply
8 balance/compensation

The 5534 is considered a very "quiet" op-amp. It has been widely used for high end audio equipment and is often seen in professional recording studio sound processing gear and consoles. You pay the price for the quiet performancewith current consumption; 6-10 mA per op-amp! VERY high, but that's the trade off you have to put up with for noise (or lack of it in this case). The op-amp can run on a supply of upto +/- 22V. Nice! At this voltage, this devicecan almost drive 1 watt of power into 600 Ohms.

Hope this is all you need. Nick

The original requester will find it educational (school of hard knocks)
or impossible to modify a cordless phone for broadcasting in the FM band.

Most of the digitally tuned radios use varactors to tune the circuits
instead of capacitors. If a source of varactors is available, then they
can be substituted for the capacitors. The appropriate circuit must be
used, in addition to the decoding, which is a simple D to A convertor.

Hello: I'm working on my first homebrew project and need to order a rheostat.

In the catalog I see there are linear taper and audio taper rheostats. What's the diffrence here?

Thanks!

Ken

1072. Making CW with a CB rig?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-05 17:37:40 UTC
From: al152511@academ01.mty.itesm.mx
Message-ID: <al152511.768159460@academ01>
Source record: 117913

Hello, homebrewers!

I have had curiosity to know if it is possible to make CW transmitting
with a CB rig quite a time ago, and have received a few advices recently,
but have not put them in practice yet.

That is because normally they suggest me to alter the rig in some manner, and
are not sure if that would work well.

I was looking for an easy way to do this trick.

I recently bougth a MFJ deluxe code practicer, that is an straight key with
an oscilator and speaker, with tone and volumen controls. This thing have a hole to connect
it to an external speaker or earphones.

I was wondering if it is possible to connect this aparatus to the entry of the
microphone in the CB like an earphone, and thus transmitting CW with the key

Muchos thanks in advice if someone can provide information about this.

73 de Ricardo Rodriguez M.

P.S. By the way, I think this would be a very interesting way of practice code
with other CBers, to get a ham license.

.

In my line of thinking, a RHEOSTAT is a potentiometer that's over the 1 watt size, usually in the tens of watts. Like the things they used to use for dimming lamps. I didn't know that they even had audio taper rheostats. Tell us more.

You can get an old Heathkit reciever or transceiver for under $100, and a good one, at that. I got my code up from 5WPM to over 20 by listening to tapes made from W1AW on my old SB303. There was an SB303 posted for sale here recently for $90. This is a great 2nd receiver to have around too. Or you can always sell it for about what you paid for it.

1075. Fox Hole Radios

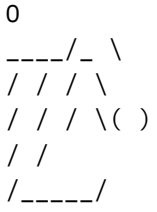
Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-05 22:05:50 UTC
From: cud@chewie.corp.frame.com
Message-ID: <2qbqju$fgs@frame.frame.com>
Source record: 117912

A long time ago, I read a Boy's Life article that
showed how to make a (veritible) chrystal radio
using a safety pin, an eraser, and a razor blade.

I recall the safety pin is rigged to connect the
circut to the razor blade at the pin point. The
eraser is run through by the pin to weigh the point
against the razor blade. You move the pin across the
surface (not the edge) of the razor blade to change
frequency.

My (most uneducated) guess is that the pin bounces
on the blade, so the current can only pass in one
direction. The bounce is related to the signal
frequency (???), so moving the pin around ressonates
differently on the blade. When you get a signal, the pin
bounces in response, so you can hear it in the ear phone.

I guess the antenna attaches to the pin, and the
ground to the blade, with the earphone in between
the ground and the blade?
This is where I get lost. I suppose I could just
try to build one of these suckers! Still, I was
wondering if anybody has heard about this low-tech
wonder, and can offer me advice.



Here is a really bad picture of the pin on the razor blade.
I didn't try to show the eraser. The parentheses are the
head of the safety pin, flattened so the pin can rotate
about a tack that holds it in place.

From somebody who barely knows how to turn on
his car radio...

Thanks cud@frame.com

The resistance is logarithmically proportional to degrees of
rotation from minimum to maximum to match the logarithmic
characteristics of human hearing.

If you build the TenTec kit, you'll be following in the footsteps of several generations of hams who started out with homebrew regenerative receivers, you'll learn an incredible amount about electronics, and you'll wind up with a receiver that will certainly be able to receive W1AW (even my bathtub gets them on occasion), although not too useful for two-way communication on the present bands. GO FOR IT!!

See my note above. Although I said that little RX won't be TOO useful for 2-way, I didn't mean it would be useless. You might decide you want next to build a QRP transmitter to go with it, and see what you can do.

See "Handbook of Radio Communications", don't remember the
author, but that book was published around 1985..86 by TAB Books.

Blade is used as a diode, not a frequency control device. Pin is
moved around the surface of the blade in order to find a good
spot where it acts as a diode.

Frequency control is done by an LC-circut at the antenna end of
foxhole radio.

Source record: 117819

The razor should be one of the 'blue steel' types. The coating or whatever makes it blue also is a different substance than the pin tip, and the two make a junction that rectifies the signal. The same thing as a galena crystal radio. You didn't include any tuned circuit, so this receiver will pick up any and all of the AM stations. Just remember that the strength of the signal is proportional to the length of the antenna.

If you go to the local Radio Shaft and buy some regular 1N4002
rectifiers, and use them instead, they will exhibit the same varactor
characteristics as the real thing, except it will not be linear as the
real thing. And of course, the amount of capacitance is dependent on the
junction size, so a higher power diode will have a higher capacitance.
Best of success.

1083. Re: rheostats

Source record: 117821

EH? I know that the audio taper has about 3/4 of the resistance in half of the rotation. And the logarithmic stuff. I guess I should have made my question clearer.

If a rheostat is a power potentiometer, then it is usually made using wire, like a wirewound resistor. AAnd the wire is heavy enough that the wiper arm can't wear it out, or tear it up.

Now how does one wind wire in an audio taper? At one end of the pot, the wire would be bunched up, and at the other end it would be spaced apart that the wiper arm would have to be extra wide, so it wouldn't lose contact. And at one end, the power dissipation would be excessive, since that's where all the resistance is.

Sounds like a rheostat might be a bit more expensive to make than the everyday pot.

1084. Re: Making CW with a CB rig?

Source record: 117822

Here in U.S.A, or E. U., it's against the law to send code over the CB. I don't know what the laws of Mexico would say. All you have to do is find the two wires in the microphone that go to the push button switch. When the two wires are shorted, then the CB set puts out power. Run those two wires to your Key. There should be no microphone on it.

The problem is in the reception. How will you be able to hear it? The CB sets do not have a BFO, or Beat Frequency Oscillator, like Ham Radios do. You will have to make up one for your receiver.

Buena Suerte.

Yep.

: Now how does one wind wire in an audio taper? At one end of the pot, the

Linear wirewound pots/rheostats can be made by winding the wire on a rectangle of thin insulating material--say .1cm x 1cm x 10cm, with the wire running across the 1cm direction. That element is then formed into a circle, and a wiper wipes along the .1cm face. If you do the same thing but make the form a triangle, or put some other taper on it, then you get a nonlinear resistance change with distance. This is _one_ way of doing it.

>as bad. Don't really know. Would it help if we used ferrite beads

This problem has occurred to me as well. Your father is probably
correct about the effect being less than that of a metal mast; but
I think that if optimum performance was my goal, I'd run the coax
along the boom to the reflector, then tape it to the back of the lower
half of the reflector and let angle away from the antenna downward to
the mast. Not a nice, clean installation, to be sure, but probably
minimizes the effect. The alternative is the counterbalanced
horizontal boom idea suggested by someone else, but if I were going
to do that my "counterbalance" would be another antenna so I could
pick up the extra 3 dB gain.

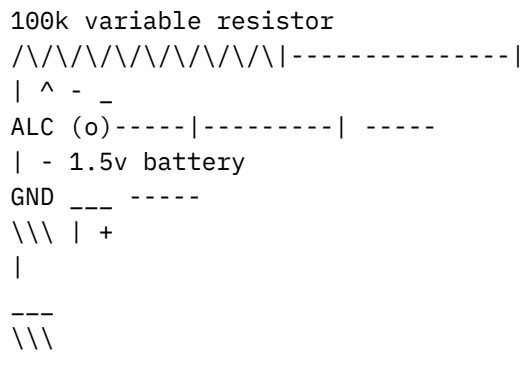
Dear Ham-Homebrew:
I don't know if this circuit would be of any interest to your readers
but it seems to be a quick way to put some of the QRO transceivers on to
QRP with power levels ranging from 5-watts down to milliwatt levels. If
you think it is worth passing on to your readers, please do!
Tnx and 72, 73 de alan

[<Alan Kaul, W6RCL>] kaul@netcom.com

(the following was distributed to QRP@Think.com on 6 May 94)

ICOM published the circuit in an ad in QST (Tech Talk# 84, QST,
Dec. 1992, Page 184) and claimed it will work for all Icom transceivers

(although I think some of the old tube types might require positive
instead of negative ALC voltage). The circuit is as follows:



Icom claims: -1.25v = 5w output
-1.30v = 300 milliwatts
-1.33v = 100 milliwatts

Common usage in electronics is that a rheostat is a two-terminal
variable resistor; a poentiometer can be connected as a rheostat
by shorting the tap with one of the ends or by leaving one of the
ends disconnected.

1093. RC motor control

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-07 22:10:54 UTC
From: mlankhei@mercury.sfsu.edu
Message-ID: <2qh3le$br7@news.csus.edu>
Source record: 117833

Hi all,

I am interested in using servo motors of the type used in model airplanes for general radio control applications. These motors rotate through an angle theta which is linearly proportional to a pulse modulated control voltage. There is a standard method of multiplexing several such data channels into a repeated pulse waveform to control several motors. The commercial systems operate in the 75MHz unlicensed RC band, but I'd like to be able to operate at other frequencies. If anybody knows anything about these servo motors, including cheap sources, please let me know. Also, if anyone knows of some good books on the subject, I'd appreciated the tip! I know there are hams out there who are into RC and operate their models in the 6 meter band, so if thats you, let me know how to get started !!! Thanks for any help.

Michael

1095. Build Hi-Pwr SS Linear

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-08 02:52:52 UTC
From: gene@eagle.csl.uiuc.edu
Message-ID: <gene.768365572@eagle.csl.uiuc.edu>
Source record: 117835

A month or two ago I suggested the possibility of home-brewing your own low-
cost High-Power Solid-state Linear on the 160-80-40 meter bands. I will report
my progress.
I will insert here, my opinion that I think this computer-networking system
is a very valuable NATIONAL RESOURCE that provides almost limitless possibili-
ties for fostering the massive, untapped creative talents of the thousands of
readers using the system.
First, I will state some of the intitial factors that I thought were attract-ive:
1. Low-cost 400v-2.5A MosFets are available for < $2 ea.
2. Full-wave rectifiying your household 230v line yields massive power
capabilites (with 10,000 ufd-200v capacitors, mine only dropped about
5% [169v to 161v] for load-current change from 1/2A to 7.5A).
3. The household "neutral becomes the circuit common"...but still remains
isolated from the case (and earth ground) by isolated pri-sec windings
on both the input transformer(from the transceiver), and the output tank
coil (to the 50 ohm antenna).
4. Since the majority of amateurs own 100 watt transceivers, you are given
the luxury of wasting drive-power to accommodate very low-ohm swamping
resistors across the inputs to the high-capacitance MosFet inputs (I
used 12-ohm, 2W carbon from each half of the Push-pull circuit to RF
ground...i.e. the forward bias line.
5. Again, because of surplus drive-power available, I used 24-ohm, 4W in
series with each end of the input transformer secondary(a 1:1 50 ohm
broad-bander, wound on a toroid), to each gate-group. Actually, the
24 ohms were two 47 ohm-2w carbon. This makes the input impedance
almost a pure 50 ohm, and makes your transceiver very happy. It also
provides a modicom of isolation against possible transients being sent
back to your transceiver when you blow your first Mosfets....yes, you
are likely to have this happen during experimentation, unless you are v

ery careful, or very lucky! With 165v stored in 10,000 uf, the MosFets
literally explode like a fire-cracker (Thankfully, my eight IRF-722's
only cost $1.50 each...yes they all go at once...but the next type I
want to experiment with will cost $1.22 ea, and I hope will go higher
in frequency.
Since this is getting quite lengthy, I will try to give a general description
of my circuit:
First let me admit that I went into this quite naiively (sp) and had several
nasty surprises, but the bottom line is that I have been on the air with a
good-quality signal providing 600W PEP out on 160 meters, and 500W PEP out on
80 meters. That's not to say that I couldn't get a little more than that,
but after a few "4th-of-July firecrackers", you get a little "gun-shy".
First, I limit my power-up surge current by using a 50- ohm, 20w resistor
in series with the rectiers and the 10,000 uf. After a second or two this gets

shorted out with relay contacts (A thermistor is not suitable here, because in SSB service, the quiescent power does not get it hot enough). Not meaning to confuse the issue, but I had used a relay with two contacts in parallel and I noticed that one closed a little ahead of the other and was getting considerable abuse, because even though the 10,000 uf gets about half-charged before the relay closes, the remaining surge-current ocurring for continuing to full charge is still large (house-lites blink slightly)..so used the first contact to short the 50-ohm, but used an additional 6-ohm which the second contact shorts out a few milliseconds later.

This is worthwhile, because so many times when one participates in a large group of amateurs, he may not contribute more that 3 or 4 minutes of talk over a 3 or 4 hour period, except to station-identify every 10 minutes. I like to power-up briefly to identify, and then turn off the linear for another 10 minutes!

I use eight IRF-722's (these happen to be by Harris) in parallel-pushpull. Each of the individual eight have a ferrite-bead and an 18-ohm, 1/4w resistor immediatley at the gate (bead slides over Fet-pin). Also, each individual source has a 2-ohm source resistor (two 3.9-ohm, 1w-carbon in parallel) , attached immediately at the Fet's source pin. For circuit common, or perhaps you could refer to it as circuit-ground, I route a #12 copper bus to within reach of the ground-end of the source resistors.

The outboard end of the 18-ohm gate resistors, are grouped...four in common for 1/2 of the Push-Pull arrangement, and the other four in the other half. These junctions then have a 12-ohm 2w carbon from each of them to a common forward bias line from a zener-regulated +5 source...with a 200 ohm pot to provide 0 to +5 to the midpoint of the two 12-ohm resistors, and I also tie the center-tap of the secondary of the broad-band input transformer to this point. I can happily report that I never saw any evidence of instability or parasitic oscillations!

My first approach used a broad-band ferrite transformer in the drain-to-drain out-put circuit. Unfortunately, there were severe glitches and wave-form distortions that were supported by this broad-band transformer...it remained the same at low power levels so am quite certain there was no core saturation etc. Actually you may find many little surprises when dealing with these low-cost high inp-capacitance MosFets....some strange phenomenon concerning "cell-to-cell propagation in the gate-capacitance" which I don't understand. I do know that when I tried a source-follower configuration using a broad-band load, I observed a myriad of clean, sharp, high-amplitude narrow pulses superimposed on the basic sine-wave!

I`m straying off the main topic....anyway, to continue, I found that my original idea of using a broad, resonant LC circuit in the output worked beautifully on 160 meters! It may be hard to think in such low-impedance terms for those used to Vacuum-tube designs, but the principles remain the same; I estimate my drain-to-drain impedance to be approximately 80 ohms. On 160 meters, my inductor was a 3 turn, 4" dia. made of 1/4" copper tubing. Each end of this had a heavy-duty type .012 uf mica capacitor from each end to common-circuit-ground. I believe the Q is approx 7 to 10... broad enough to cover 1.8-2.0 MHz. The output secondary is simply a wire with good-quality insulation, threaded thru the copper tubing and connected directly to the output coax connector....which is case ground (earth ground)

Incidentally, the earth-ground (green-wire) of the household power also connects to the case. Parenthetically, I didn't take time to run a conventional 230 connector to mine...I simply used two 3-wire 120 power cords plugged into two different outlets in the room which had opposite phase (be sure to verify correct phase and use only polarized 3-wire plugs).
The distortion was purified beautifully by the resonant LC circuit on 160 meters. Unfortunately, using similar Xc (Q) on 80 meters did not clean up the wave form to an acceptable degree. I first added a 5-element Chebychev 50-ohm filter from the ARRL Handbook. It still was not quite clean enough, but when went to 7-element (4 inductors, 3 capacitors) it cleaned up nicely. I used a small size coffee-can (with its cut-out bottom-piece tack-soldered in the center for the middle capacitor and two middle inductors, then added same-diam smaller- height cans for the outside ends (Peanut cans??)...this provides shielding between air-wound inductors. `Didn't bother covering outside ends. I had tried a smaller ferrite toroid from the junk box, but they got very hot at 600w and probably saturating.
On 80 meters, about 40 watts of drive was required to drive the linear to 500w PEP out. Of course most of this is arbitrarily wasted, and it`s quite likely that it could be successfully driven with much less...probably with the smaller-power transceivers with plug-in modules now offered by TenTec for around $500...called the Scout, I believe.
One more construction feature worth mentioning....the four MosFet drain-tabs in each group are mounted directly on one of the two large heatsinks. Of course the heat-sink itself must be insulated for at least 350 volts, but stray capacitance is of no concern at these low-impedance, lower frequencies (witness the .012 uf from each heat-sink to ground).
I do use a small muffin blower fan and that's always desireable, but mine run so modestly warm that I'm not sure it's an absolute necessity if one avoids long "key-down" carrier. MosFets seem to operate with amazingly low quiescent current requirement to eliminate cross-over distortion!
I apologize for such a lengthy posting... I hope there's enough general interest to justify it. I hope many will "put their toe in the water" and post any new observations of interest to the net. I have learned quite a bit (albeit the hard way) and plan to soon experiment with a further idea: There are probably better MosFet options that I'm not aware of with my rather isolated environment, but one that I'm interested in is the Motorola MTP-1N60. It is a 600v-1A, that appears to have switching characteristics considerably faster. It's drain-to-drain impedance would probably be about 4 times as high, which would be more practical for the LC output resonant tanks, with a convenient 4:1 stepdown broad-balun to match the 50 ohm antenna. The 240v line (120-0-120) would need to be negative-rectified also to provide 320vdc. Of course, the "circuit-common" would now be down at the -160v level, but don't believe this would be a problem because of the isolation provided by the input and output scheme as mentioned above.
It is my belief (naiive tho it may be) that the higher-speed switching characteristics do not get compromised, even though many MosFets are connected in parallel; only the drive requirements must be dealt with, but again, with much reserve power from the transceiver, and with the higher-speed transistors having lower input capacitances, I think it is quite

practical to consider using as many as 10 or 12 to easily get 1Kw PEP out. With my experience-to-date, it appears that as long as you put the individual ferrite-bead and lo-ohm resister at each gate, stability is maintained. Also, Mosfets on the same heatsink, have the fortunate feature of heat-shifting if they get much disparity. Even though the "quiescent" isn't quite as fortunate, with many in parallel...and with the remarkabley-low quiescent current requirement....my meager experience so far seems to be that it's no problem even when all are biased off a common bias-line.
One more last thought as long as I've gone this long....I plan to put a simple SWR bridge in the output line, so that if the SWR gets to an unacceptable level, it will cause a transistor on the forward-bias line to conduct and kill the forward-bias (this is 3.5 volts in my case).
Unlike vacuum-tubes, MosFets are rather unforgiving and after a few milliseconds, it's too late. Which reminds, I didn't mention above that I put a pair of back-to-back zeners from each gate-group, to circuit-ground (total of 4 15-v zeners). Even though this includes the drop across the emitter-resistor, it's still within the bounds (+ or - gate to source breakdown voltage-limit). ......Finally, the END!

Well, if it's at DC, then it's called a power supply. If it is at 100MHz, then it's called a transmitter. You probably won't find a device that will go much more than 1 or 2 decades, for a reasonable price.

The voltage at 100MHz, let's say, it 100 volts. At 100KHz, it would be a tenth of a volt. What would it be at DC? Microvolts? This device you want would have to be lon-linear to meet those requirements.

No. RTTY is narrow band FSK. Modems don't do that narrow a band,
but use as much of the the full 300 to 3700 Hz bandwidth as they can.
They actually put out an audio carrier. What you want to do is shift
your RF carrier with the RTTY signal. So the RTTY pulses would be fed
into the transmitter oscillator or VCO. If you have an RTTY, it probably
puts out current loop, and most modems don't handle current loop.

The closest chip I can think of is the Motorola MC1648 (I think thats the right number). You can make a reasonably good varactor tuned VCO out of it. DC to 100 MHz would not be practical for a single oscillator though.

Generally, that kind of tuning range can be had by mixing
two UHF oscillators together and taking the difference between the two.
One oscillator would be fixed, say at 500MHz, the other would be tuneable from 500 to 600MHz. This allows wide tuning range and good linearity.

Hope that helps

Steve Muther WF6R stevem@w6yx.stanford.edu

1103. Metal-Encased Mica Caps

Source record: 117843

A HT Amp I bought (RF Concepts) uses these funny capacitors in the RF circuits. They look like a collection of bits of mica and other stuff, clamped in a little metal frame. They are between 1/4" and 1/2" on a side. I also just got a "Surplus Sales of Nebraska" flyer, which lists some of them for sale.

I was wondering: what is the advantage of this type of device? They look sort of crude, with an open construction that could let solder, moisture, etc. get in and mess them up.

The popular Mini-Circuits SBL-1 uses a little surface mount mixer ring
in its mixers. Usually, surface mount devices work better than leaded
devices in terms of switching speed, though you sometimes lose a bit
in the power handling capability.

Supposedly, the best diodes to use in DC receivers are those optimized
for low 1/f noise. I think mesh diodes were designed for this purpose.
Otherwise, the mixer may be noisier than you might expect from the
conversion loss.

If you buy diode pairs or quads, make sure they are hooked up the way
you want them to.

>Joe - AA3GN

Just to clarify: I agree with Joe's remarks. An older radio that's
inexpensive merely because it's used and perhaps lacks all the fancy
digital features, etc., but is otherwise servicable meets my definition
as "real". My suggestion that one should not buy something cheap was
in the context of discussion of one of those $30 kits designed solely
for listening to W1AW.

For VHF/UHF, meaning above 6m, you'd probably need 'real' power RF MOSFETs,
such as the MRF171, etc. These are fairly pricey, but offer high gain and
a lot of power, but they are fairly easy to fry. I'd suggest getting your
feet wet with the less expensive bipolar transistors, such as the 2N5590,
or MRF1946. These are more rugged and would make a better beginner project.

For HF and VHF-low (meaning 6m), you can probably get really good results
with conventional switching FETs. The IRF510 (or IRF511) is easily available,
cheap, and offers good performance to 60MHz. You can expect between 5-20W
output, depending on frequency and circuit design. There have been articles
in QST and other mags, also, look for Doug DeMaw's QRP Notebook at a ham
store. I've had an MTP3055E deliver 40W of RF at 14Mhz with about 500mW of
drive. Good stuff, but don't go for max power if you want the part to last :=).
On the other hand, replacements are about $1, so what the heck?

1111. Need Help with homebrew repeater design

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-09 19:11:23 UTC
From: paul@tc.fluke.COM
Message-ID: <CpJun3.1pE@tc.fluke.COM>
Source record: 117852

I'm interested in putting together a simple temporary repeater using two back-to-back transceivers. I would rather not have to tinker with the circuitry inside the radios, so I want a circuit that can detect whether the squelch is open or closed from outside the radio.

One scheme I've seen for doing this takes the discriminator output on the microphone jack and runs it through a high-pass filter. Apparently an FM discriminator which is not receiving a carrier emits some very high frequency audio and the idea is to detect this "hiss" and use it to determine the state of the squelch.

I have a discrete design for this that I could copy, but I'm wondering if there are any ICs out there that might perform this function for me. It seems like something that might be used in the cellular or commercial radio world.

Anyway, if you know of such a device or have any suggestions of other non-invasive techniques that might work, please pass the info along via email. Thanks in advance.

Paul,
KE7XT

I've wondered about this too. It seems to me that a power MOSFET would not be a good choice for a class C amp. Power MOSFETS have a "parasitic" diode that is connected from drain to source. This diode is an artifact of the manufacturing process. In most applications this diode is reverse biased. But what happens in class C service when the drain swings negative (for N channel mosfet)? Wouldn't this intrinsic diode tend to clamp negative swing on the drain? It would degrade the efficiency and Q of the output network, I would think. I guess class A or AB service might work.

I have the 1988 Directory Issue of RF Design. The article is listed as
"A Simple Spectrum Analyzer," Albert Helfrick, Jan. '88 , p. 35

Somewhere I must have the article, but it's not in its place.

Umm... under normal circumstances, the drain doesn't swing below ground.

I've built several power MOSFET RF amplifiers, mostly with IRF511 and
MTP3055E. They all worked quite well. Using a 24V drain supply results
in greater efficiency and higher output power. I could get 35W+ out of
an MTP3055E on 20m with maybe 500mW of drive. I never managed to find a
really good input match; it was always about 2:1, which isn't awful. A
-3dB pad would improve it a little.

1116. *****Ideas sought for a 400MHz oscillator design*****

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-10 08:17:42 UTC
From: snorris@harp.aix.calpoly.edu
Message-ID: <1994May10.081742.173886@zeus.aix.calpoly.edu>
Source record: 117855

I am working on a senior project that requires the use of a 400MHz sine wave local oscillator. This oscillator will be used to construct a portable, multi-band frequency converter which can be placed on a handheld amateur radio.

My question is: Does anyone have any ideas for generating a 400MHz sinewave? It should be capable of delivering about +7dBm into 50 ohms and be able to run from a 7.2V battery.

I have looked around a bit, but have yet to find anything that really goes up that high in frequency. I have kicked around a few ideas, but I wanted to see if anyone here had some good ideas before I started trying circuits.

Also, I would rather the circuit use lumped elements (i.e SMD) because I want to keep the circuit absolutely as small as possible and I think distributed elements would make it too large for what I want.

So if anyone has any circuit ideas or can suggest some good references, then please E-mail me as soon as possible.

Thanks in advance,

Sean

Sean Norris snorris@trumpet.aix.calpoly.edu

Sean,
Build a 130 MHz oscillator and use a frequency tripler. Works fine. The
tripler can also amplify your signal up to your requirements ; the
oscillator is not loaded anymore, so it is far more stable.
It&#65533;s the way I&#65533;m going to cope for a home-made VHF/UHF all mode TX.

Hi !

I have been scared by the price of the latest VHF/UHF all mods rigs. So
I decided to build my own. However, I m looking for a UHF Push-Pull design.
The very problem I have is in the design of the 180 degrees phase shifter.
In VHF, I can use a small transformer with a ground tap in the middle, but
this cannot be applied to UHF. I thought about a printed transformer or a
transistor operating as an inverter. Neither those seem really satisfactory.
Does someone have any clue ?

Thanks and 73 !

Vince.

In class-C type operation you won't find the drain voltage swinging negative. Ignoring the FET on-resistance, the average drain voltage would simply be the DC supply level, V, and in operation the drain voltage would swing from 0V to 2V. Practically, the device on-resistance limits the downward swing to a few volts, however. Therefore it's better to use high supply voltages for FETs (ie. higher than 12V), to increase the voltage swing available.

Quite a good way to drive FETs is a simple complementary emitter-follower pair. This configuration can provide sufficient current to charge/ discharge the effective gate capacitance, which can be large for power devices being switched on/off. The only
problem is getting hold of a PNP device with high ft. It does save messing about with matching networks, though.
Motorola note AR-141 in their RF Device book give good info on this subject, with regard to driving class-D/E DMOS FET stages.

For low power HF operation, switching FETs have a lot going for them. They are very easy to bias, cheap, they don't exhibit thermal runaway and it's easy to drive them.

Good luck,,

Simon G0GWA.

December 1986/QRP Classics has a HF QRP transmitter design by Mike Masterson. It is class C with very good efficiency. The Siliconix application notes characterize the diode as having a slow recovery speed (200 to 400 ns), which means it is too slow to switch on and cause problems at HF. The gate capacitance of cheap FETs is quite high, which makes them tougher to use at higher frquencies.

The November 1989 QST Technical correspondence piece by Hayward is worth reading. Interestingly, a ferrite bead can destabilize a FET amplifier (contrary to some people's opinion). It recommends low impedance, non-inductive terminations for class A amplifiers.

>So if anyone has any circuit ideas or can suggest some good references,

There are two basic approaches to your problem. First is a crystal osc.
and multiplier system. The other way is to use a VCO and PLL system.
In today's world, the PLL/VCO system would probably be the winner since
it would be about the same size as the osc/mult and offer the additional
feature of frequency agility. Consult recent data and applications books
for Fujitsu, Philips and Motorola PLL Synthesizers for details.

Also, you mentioned the need for the oscillator to be a sine wave. It
sounds like you may be driving a balanced mixer in your converter. By
nature, the diodes within a balanced mixer square up an incomming LO
anyway. Those mixers will work just fine being driven by something
less than a pure sine wave and, in fact, I have seen designs where
the mixer was driven directly by an ECL square wave and the mixers
are quite happy.

There may be some basic theory in the new ARRL microwave experimenters
manual.

Here's another interesting article:

"80m Radio Transmitter uses power MOSFETS" (Design Ideas section)
by Robert G Culter (N7FKI) EDN, November 28, 1985, p280.

This uses an MPF910 as a crystal oscillator, followed by an MTP12N10
power amp. He claims the puppy will put out about 45W, and you can
(or could in 1985) build this for less than $20 (color burst crystal).
One of the interesting features is that he uses the Ciss of the amplifier
as part of the feedback for the oscillator. He also claims that he got
84% efficiency out of the output stage.

I wonder if it chirps; kind of hard for me to believe a 2-stage rig
putting out 45W wouldn't...

Look at the receive converter for 440 MHz ATV which is included in recent editions or the ARRL Handbook. It uses a VFO oscillating at just under 400 MHz. However, the layout is critical. I built mine dead bug style and had to move things around a bit. Watch ground capacitances if you want to reach 400 MHz or above. I used 1/4" square pads of circuit board glued to the ground plane for support. As a result I had to make the inductor smaller than in the article.

...stuff killed...

Sean:

What do you want?...a VCO or what? You have to be more specific. The level which you mention tells me the you will be running a standard DBM. Did you ever consider using an actice mixer/VCO made by a number of companies...like SIgnetics/Philips. Using these 'builing blocks' will greatly reduce the size you can expect your RF deck to be. Of course, they are available in surface mount too.

Sure just use a halfwave of transmission line as a very simple balun. It
works for antennas, and it'll work as a push-pull input network too.

Yup. And you can, if you wish, insert a protective diode in the drain
circuit.
FET are ideally suited for class E operation - Class AB is also possible, and
if you want to build a SSB rig anyway, I don't advise you to use class C :-)

For further info consult Motorola Application Note AN860. As a general rule,
FET have more stable input impedances, but are not really suited for low-power
applications (due to Drain-source saturation voltage).

Dean

Any diode will act as a variable cap when reverse biased. The doohickies sold as 'varacters' have a wider response and more closely specified properties, but for experimentation any diode will do. I had good results fine tuning a SW receiver using the first small-signal diode I grabbed out of the junk box. The non-conducting region in the reverse-biased diode acts as a dielectric between the terminals; this is the cap. Varying the voltage changes the thickness of the non-conduction region, and thus changes the capacitance.

I bought some Siemens BB104 (back-to-back pair varactor) diodes from Fertiks Electronics in Philadelphia ((215)455-2121) a while ago. They sell them at six for a dollar, can't baet that!. You can also get the popular kinds (MV21** and MV22** series) at Dan's Small parts place.

I have the following INSTRUCTION/OPERATORS MANUALS up for grabs:

HY-GAIN THUNDERBIRD (TH3Mk30 THREE ELEMENT HAM ANTENNA

CDE HAM II ROTOR

These INSTRUCTION/OPERATORS MANUALS are in various states of condition. Some are in good condition and some are in poor condition.

The intent is to give these INSTRUCTION/OPERATOR MANUALS to an individual or entity who ACTUALLY has the equipment.

The first person to send me e-mail gets the booty. Please send a separate e-mail request for each INSTRUCTION OR OPERATORS MANUAL. You will be asked to send a SASE (large manila or other envelope) with the appropriate amount of U.S. postage to me c/o the address in my .sig file.

Good luck to one and all.

73,

~jack_

>low impedance, non-inductive terminations for class A amplifiers.

I recall that DeMaw has often suggested using ferrite beads on the gates of power FETs. I stopped doing this after I thought about it for a few moments. This strikes me the same as the "common wisdom" about putting Zener diodes on the collectors of HF amplifier transistors to protect against SWR induced damage. I've never actually measured the time it takes a common 40V Zener diode to start conducting, but I tend to think it is far too slow to clamp an RF wave. I decided the Zener was simply a source of capacitance. Later, I read Roy's (W7EL) letter in QST (also in the QRP Classics ARRL book) which examines the high voltage ringing at the collectors of VHF transistors used in class C amplifiers. Roy speculated that the use of Zeners adds capacitance, which eliminates the ringing.

I'll follow this note up with another regarding the gate capacitance of a power MOSFET....

1136. Need info about packet Ham Radio - FAQ anywhere?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-12 01:05:28 UTC
From: Martin.Stephenson@cscgpo.anu.edu.au
Message-ID: <Martin.Stephenson.6.00011765@cscgpo.anu.edu.au>
Source record: 117770

I am looking for any info about packet ham radio. Like where can I find an FAQ? :-) I am pretty well after enough information to get someone started with packet ham radio.

My Father was a keen Radio Ham until he moved to Egypt. The easiest way to access the Internet from Egypt would be via Ham radio. The Egyptian telecommunications system stopped being developed sometime in the stone age, and so normal access methods are not economically possible.

I thought this group might be a good place to start to find out more about packet ham radio.

Thanks for any help.

Martin.Stephenson@anu.edu.au

There is a Philips Dream Machine 8XC750 design contest.

If you have ordered their DS-750 toolkit and have figured out what to do
with it or are trying to figure out what to do with it, request to join
the mail list that I have started.

To join send mail to the following (manual) mail server:

DS-750-request@stardust.oau.org

I received my development kit yesterday and am impressed with the contents.
While it comes with a debugger, I wonder if any assembler or compiler for
the 80C51 could be used with it?

I do not work for Philips or any semiconductor manufacturer.

best regards,

If you are contemplating spending $300 or so on a Radio Shack SWL receiver,
take a look at some of the old military stuff (R390, etc). You'll get a lot
more (weight, size, quality) for your money. Some of the more recent stuff is
starting to show up on the market for $500 and above...I've seen Racal stuff
and even some Watkins-Johnson. Check Fair Radio in Lima, OH for the surplus
stuff (if you have room and $ for the shipping :-)

: Any thoughts on temperature compensation for this? ...

The problem is that quartz crystals do not have a linear frequency
versus temperature curve. Standard AT-cut crystals are generally
manufactured so that the inflection point in the F vs t curve is
flat at room temperature. So no compensation is needed so long
as you stay close to room temperature and the rest of your circuit
doesn't degrade crystal stability.

Crystals intended for use in temperature-controlled ovens are designed
to have a flat inflection point at the oven temperature.

Let's see if I can do an ASCII graph of an AT-cut crystal's frequency
versus temperature curve:

```
\
^ \
| \
| \
Freq \
\
-
- _
---------- _
-
-
\
\

1147. Walkie-talkie for data transfer

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-13 08:24:44 UTC
From: Nils-Olof.Svensson@Geol.lu.se
Message-ID: <Nils-Olof.Svensson.34.768817484@Geol.lu.se>
Source record: 117786

I am in the precess of planning the design of electronic barometre for field measurements of altitude (no comersial things, only for my use).
To compensate for drift due to weather changes I need to use two instruments one at a fixed point of known altitude and one I am walking in the terrain with. Either I can have a computer or a person recording values at the fixed station, but better would be to radio transmit data the maximum 2 km to the second unit. To do it cheaply I am thinking of using two Walkie-Talkies for this, the measured voltage at the fixed station should be converted into a voltage depending frequencie and fed into the microphone and transmitted. The receiver gets the frequencie, converts it back to voltage and ads it as a offset to measured pressure value wich then are displayed by a digital volt metre.
As I know nothing about radios etc I am sure there could be some problems, such as: which audible frequency interval is best to use?, can the sent freq. be a square wave or is sinus better?, can I connect directly to Microphone and speakerconnections or would an Optic or audible coupler be better? How to eliminate or reduce noice?, Will a Walkie-Talkie manage to transmit continously for a day (with a large battery)? Is there a better solution?
Any hints to these questions or other complications would be most valuable.

Best regards

Any diode has a capacitance which varies with reverse bias. However,
small-signal diodes like the 1N914 have a very small capacitance. Zeners,
on the other hand, have much more and are excellent for general use.
The lower the zener voltage or greater the power rating, the greater
the capacitance. Of course, you shouldn't exceed the zener voltage. (If
you do, no harm will be done if the source is current-limited at a reasonable
value, but the "capacitor" will suddenly get very lossy!) I haven't tried
it, but the emitter-base junction of an ordinary small-signal transistor
should work reasonably well, since most break down at around 4-6 volts
of reverse bias.

From: royle@tekgp4.cse.tek.com
Message-ID: <2r0f49$ggr@tekadm1.cse.tek.com>
Source record: 117788

myers@spot.West.Sun.COM (Dana Myers):

;I recall that DeMaw has often suggested using ferrite beads on the
;gates of power FETs. I stopped doing this after I thought about it
;for a few moments. This strikes me the same as the "common wisdom"
;about putting Zener diodes on the collectors of HF amplifier transistors
;to protect against SWR induced damage. I've never actually measured the
;time it takes a common 40V Zener diode to start conducting, but I tend
;to think it is far too slow to clamp an RF wave. I decided the Zener
;was simply a source of capacitance. Later, I read Roy's (W7EL) letter in
;QST (also in the QRP Classics ARRL book) which examines the high voltage
;ringing at the collectors of VHF transistors used in class C amplifiers.
;Roy speculated that the use of Zeners adds capacitance, which eliminates
;the ringing. . .

The zener capacitance can be enough to eliminate the ringing, but zeners
are fast enough to limit the peaks and protect the output stage from
temporary fault conditions like transmitting with the antenna disconnected.

I am also interested in the answer to this question.
Also, are there c compilers for the 80c51 series?
I have a project in mind for the 8xc752, but the
math is a problem for the assembly code.

If you are associated with a college or university, the obvious thing to do is order a Xerox copy through your library's interlibrary loan service. They will have another library find it, copy it, and send it to them for you.

Some public libraries also do this.

You may get more responses by posting this to the
rec.radio.amateur.homebrew newsgroup.

The radio transmitter will need a modem between the data source and the
microphone. Connect the serial data to the transmitter of the modem, and
use a volume control to reduce the level. The modem puts out a tone that
will work with the walkie talkie's microphone.

You didn't say how much data you will transmit, but it will
be better and easier for the receiver if the data is transmitted slowly.
The receiver will need the same kind of modem, connected to the speaker
output. Older modems that run at 300 BPS or 1200 BPS should work. By
the way, they put out sine waves, but the modulation can make the sine
wave do some very strange things.

It sounds like you are trying to eliminate having another human being on
the other end of the RF link. You could have a tape recorder connected to
the receiver on the far end, and just speak the data into the microphone
of the walkie talkie. Later, you could record all the data on your
computer. This takes more time, but it might be more reliable. 2 Km is
quite a long distance for a pair of walkie talkies to receive over.

Maybe you could use solar power if you are concerned about battery
lifetime.

On many HF radios, the lower frequency has a certain setting because just
below it is the first IF frequency. If you try to lower the receiving
frequency, the radio will just receive its own IF or local oscillator
frequencies. The radio will oscillate or just won't work. If you look
at the specifications for your radio, you may find that the first IF is
not too far below the lowest receiving frequency, 3850 KHz.

>David Billsbrough
>kc4zvw@stardust.oau.org
David,
According to Phillips IC20 Data Book on 80C51-Based microcontrollers,
in the 8xC751 overview
"PLEASE NOTE: The instruction set of the 83C751 is
identical to the 80C51 except for the instructions:
MOVX, LCALL, and LJUMP, which are not implemented.
Care must be taken not to use any of these instructions
in a user program, especially when using a high level
language such as C."
So if you're using an assembler, just avoid those instructions. If you
want to use a C, there *might* be a way to force your compiler to not
use the LCALL and LJUMP instructions. I ues Franklin's C compiler, and
using the #pragma ROM(COMPACT) forces the compiler to use ACALL and
AJUMP.
Hope this helped.

Or he may find that the European version of this radio covers a narrower version of frequencies than the American one and that he can convert it into the American version by changing a jumper. I'm not at all sure whether this is the case with the 7600, but it's worth looking up.

Contact: Pan-Com International
A Division of Pan-Axis Productions
P O Box 130
Paradise, CA 95967-0130
Tel: 916 534-0417

They have a variety of PLL (digitally tuned) FM exiter kits that run
anywhere from 1/2 to 10 watts, mono or stereo. You can buy plans only,
plans + PC board, complete kit, or assembled unit.

For example, their FME5 has the following specs:

Freq: 87 - 109 MHz in 25 kHz steps (PLL)
Output power: Adjustable up to 5 Watts
Spurious Outputs: -40 db
Audio Response: 20 - 90,000 Hz
Audio input: 600 ohms
Mode: Mono (stereo generator available)
RF output impedance: 50 to 75 ohms

The complete kit costs about $200 less power supply & cabinet.
It requires +12 and -12 volts at 650 ma. Plans only are about $25.

Changes: new mailing lists, .packet rmgroup, and .policy updates

(Note: The following is reprinted with the permission of the author.)

This message describes the rec.radio.amateur.*, rec.radio.cb, rec.radio.info,
and rec.radio.swap newsgroups. It is intended to serve as a guide for the new
reader on what to find where. Questions and comments may be directed to the
author, Jay Maynard, K5ZC, by Internet electronic mail at
jmaynard@oac.hsc.uth.tmc.edu. This message was last changed on 18 September
1993 to add the mailing lists for the new rec.radio.amateur newsgroups, to
note the rmgroup of rec.radio.amateur.packet, and to officially retire some
(in)famous threads of discussion on rec.radio.amateur.policy.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list
for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions
were held on the mailing list, and sent to the mailboxes of those who had
signed up for it. When the Usenet software was created, and net news as we
now know it was developed, a newsgroup was created for hams: net.ham-radio.
The mailing list and the newsgroup were gatewayed together, eventually.

As the net grew, and as packet radio came into vogue, packet discussion began
to dominate other topics in the group and on the list. This resulted in the
logical solution: a group was created to hold the packet discussion, and
another corresponding mailing list was created as well: net.ham-radio.packet
and PACKET-RADIO, respectively.

These two groups served for several years, and went through Usenet's Great
Renaming essentially unchanged, moving from net.ham-radio[.packet] to
rec.ham-radio[.packet]. Readership and volume grew with the rest of the
network.

The INFO-HAMS mailing list was originally run from a US Army computer at
White Sands Missile Range, SIMTEL20. There were few problems with this
arrangement, but one was that the system was not supposed to be used for
commercial purposes. Since one of hams' favorite pastimes is swapping
gear, it was natural for hams to post messages about equipment for sale
to INFO-HAMS/rec.ham-radio. This ran afoul of SIMTEL20's no-commercial-use
restriction, and after some argument, a group was created specifically
```

for messages like that: rec.ham-radio.swap. This group wasn't gatewayed to a mailing list, thus avoiding problems.

While all this was happening, other folks wanted to discuss other aspects of the world of radio than the personal communications services. Those folks created the rec.radio.shortwave and rec.radio.noncomm newsgroups, and established the precedent of the rec.radio.* hierarchy, which in turn reflected Usenet's overall trend toward a hierarchical name structure.

The debate between proponents of a no-code ham radio license and its opponents grew fierce and voluminous in late 1989 and 1990. Eventually, both sides grew weary of the debate, and those who had not been involved even more so. A proposal for a newsgroup dedicated to licensing issues failed. A later proposal was made for a group that would cover the many recurring legal issues discussions. During discussion of the latter proposal, it became clear that it would be desirable to fit the ham radio groups under the rec.radio.* hierarchy. A full-blown reorganization was passed by Usenet voters in January 1991, leading to the overall structure we now use.

After the reorganization, more and more regular information postings began to appear, and were spread out across the various groups in rec.radio.*. Taking the successful example of the news.answers group, where informational postings from across the net are sent, the group rec.radio.info was created in December, 1992, with Mark Salyzyn, VE6MGS, initially serving as moderator.

In January, 1993, many users started complaining about the volume in rec.radio.amateur.misc. This led to a discussion about a second reorganization, which sparked the creation of a mailing list by Ian Kluft, KD6EUI. This list, which was eventually joined by many of the most prolific posters to the ham radio groups, came up with a proposal to add 11 groups to the rec.radio.amateur hierarchy in April 1993. The subsequent vote, held in May and early June, approved the creation of five groups: rec.radio.amateur.digital.misc (to replace .packet), .equipment, .homebrew, .antenna, and .space.

The Current Groups

I can hear you asking, "OK, so this is all neat history, but what does it have to do with me now?" The answer is that the history of each group has a direct bearing on what the group is used for, and what's considered appropriate where.

The easy one is rec.radio.amateur.misc. It is what rec.ham-radio was renamed to during the reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize

this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, should be removed by September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is now rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there.

The first reorganization added two groups to the list, one of which is rec.radio.amateur.policy. This group was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The other added group is rec.radio.cb. This is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently Mark Salyzyn, VE6MGS. The email address for submissions to the group is rec-radio-info@ve6mgs.ampr.ab.ca. Inquires and other administrivia should be directed to rec-radio-request@ve6mgs.ampr.ab.ca. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas,

commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

1163. What are these chips?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-15 14:32:43 UTC
From: denglet1@iia.org
Message-ID: <2r5bqb$36u@mary.iia.org>
Source record: 117802

I have about 40 or so old circuit boards with some socketed chips that I was wondering what they might be good for. Can anyone can give me a brief functional description of these chips? I presume they are coming from something like a mainframe modem. If so, it would be nice to build some ham modems if posible, or perhaps a PC controlled antenna for tracking satellites. Or are they destined to be a very small boat anchor? I hate to throw them away, I am sure they would like to do some more digital work.

[1] AM2910BPC - 40 pin - 3 of these on each board.
8405DM

[2] AM2910DC - 40 pin - One of these, is this the same as the 8345DM prior chip [1]? Is the 8345DM just a date?

[3] Z80A CPU - 40 pin - I know this is a Z80? What is a good source of playing with this chip?

[4] N82S147N - 20 pin - 5 per board. with these additional second line numbers: D1N 48 REV A
D0N 48 REV A
HP0N48 R A
HP1N48 R A
HP2N48 REV.A

[5] MB7124E - 20 pin - 1 per board
HP3N48RA

[6] TMS - 24 pin - See through window on top
2516JL-35
MFP8401

There are also a gadzillion soldered chips on the boards. Mostly 74 series hex inverters, gates, etc. which I do have info on from the TLL cookbook. What is a good way to remove these guys if I wanted to?

What is a good source to find info on these chips?

It's extremely unusual to have more than one 2910 per board - are you sure none of them are 2901's? I've made that mistake... Anyway,
The 2910 is a 12bit microcode sequencer from AMD. Basically, it's a chip for generating the addresses for the internal control program of a microcoded CPU. It contains a 4-level subroutine stack, and the program counter. The problem with it is that there is no easy way to cascade more than 1 of the chips to have more than 12 bits of address. Otherwise, it's quite a useful chip if you're into designing your own processor.
The 2901 is a 4-bit ALU and register bank. Again, only useful if you're designing a CPU.
Both those chips are from AMD. I think they're being discontinued soon.

>
>[3] Z80A CPU - 40 pin - I know this is a Z80? What is a good

Yes, 4MHz Z80 CPU. Look at the Zilog data sheets for more information

>

512 byte * 8bit PROM. Probably useless as it's already been programmed.

>series hex inverters, gates, etc. which I do have info on from the TLL
>cookbook. What is a good way to remove these guys if I wanted to?

I've perfected (?) the art of unsoldering a chip from a through-hole-plated PCB and leaving both the chip and board in one piece. However, that's non-trivial to do. If you just want to remove the chips, and don't care about the board, I'm told that a hot-air paint stripper, or a propane torch will melt the solder quickly enough to let you pull the chips. I've never tried it, as in most of the jobs I do, the board is by far the more valuable part.

>
>What is a good source to find info on these chips?

Manufacturers data books. They cost about $10 each, so buying enough to cover all the chips you are likely to meet is non-trivial. Sometimes you can find old copies being cleared out (say by companies or universities), and they'll give them to you. No good for the latest stuff, but great for things like Z80's, TTL, etc

AMD microcode controllers for the 4-bit 2901 bit-slice and 16-bit 2903
series bipolar CPUs. The 2901, if memory serves, first appeared in
the early '70 or mid-70. The 2903 late-ish 1970s.

Don't confuse these with the 29000 family, which are embedded RISC
processors that came much later.

Around 100 ns per instruction, plus or minus how much extra you paid.
Much harder to program than standard processors of its generation, even
the 8080 and 6502 from them days. I don't know many people who wrote
microcode for the 2900 who are still sane :-). At Stanford, they made
grad students (me) do it. We were using these to build fast FFT machines
to look for Extraterrestrial Intelligence. No one answered our CQ DXx :-).

The "8405" sounds like the chip was packaged on the 5th week of 1984
and the "8345" indicates the 45th week of 1983.

>[4] N82S147N - 20 pin - 5 per board. with these additional

These are either Signetics bipolar fusable-link ROMS or bipolar RAMs.
I no longer remember which the 147 is; too many cosmic ray hits on my
own memory cells. The fuses of early batches of these ROMs had the
irritating tendency to grow back. Who knows, by now, you may be able
to use the chips on your board as if the fuses are fresh :-) :-).

Just kidding, they did grow back, but quite rarely.

>[6] TMS - 24 pin - See through window on top
> 2516JL-35
> MFP8401

Sounds like Texas Instruments' version of the 2716 EPROM, 350 ns
access time. 8401 again a date code - 1st week, 1984. Do you see a

TI logo (little map of the Republic of Texas) on it? 16 kilo bits
(no, not bytes -- we are talking about the stone age, remember?)
worth of erasable memory. I don't completely remember now, but there
was something quirky about the 25xx series. Was it that it needed
a +12 volt supply in addition to +5 volt?

Maybe you can use these parts to build a spark transmitter. Read
the issue of the Spring '94 "Communications Quarterly" that just came
out if you want hints on how to build a modern spark transmitter (oops,
I hope I didn't wake Jeff, NH6IL, up from his lounging on the Waikiki :-).

There are some major component errors in this schematic. The R5 and R7 should be more like 4.7K and not 47K. The value of the RF tank coil is stated to be 1 uH, but it should be more like .08 uH, however the winding instructions are about right. The value for R6 is missing from the parts list. It should be in the hundreds of K to 3 Meg range, whatever sets the voltage of the collector to 4 or 5 volts. There is no preemphasis on this circuit, so it will sound muffled on the receiver. It would be a good idea to check the following months of the magazine for circuit error corrections on this project, however, some magazines don't even bother to publish them ("we don't make mistakes").

A followup to my followup on the FM transmitter. The two transistors are hard to find anywhere, I guess the numbers are euro speak. But the audio transistor for the microphone can be a 2N3904, available at Ratio Shaft. The Rf transistor can also be a 2N3904, but it should not be run at the current that this circuit allows. The emitter resistor should be increased from 100 ohms to 220 or 330 ohms to reduce it. THe 2N2222A or PN2222A can also be used here. It's R-S cat no. 276-2009. The 2N3904 is 276-2016. I have some reservations about the RF stage, because it doesn't have some small capacitors to swamp out the transistor capacitance. This means that the transmitter will drift with temperature changes.

For some time now, I have been trying to modify an FM broadcast band tuner I have to make it super-selective. My problem is that I can't get the ajacent channel selectivity I need using ceramic filters. I have enough gain in my IF stage that I can cascade quite a few of the things, but I still can't get enough selectivity without cutting into the passband I need.

So, this is my question: Does anyone know of a source of say, crystal filters or any other filters that could give the selectivity I need. The center freq. is 10.7 mhz and the bandwidth is 200khz for those who aren't familiar with FM tuners. Any help is appreciated.

This may be a little hard to believe, but I use a propane soldering torch; yes
torch not an iron. Actualy a heat gun is better but a torch will suffice.
I have use this method to remove thousands of ics, and other components
from PC boards and have about and 60-70 % success rate.

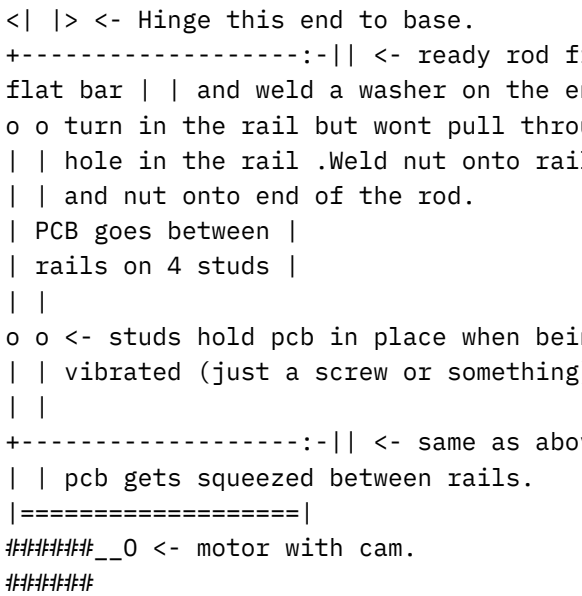
Method :
drill holes in board along edges, preferabley in the corners.
place board on to a jig that you have made from metal (what ever kind
that you can work with) . details on this jig will be explained later.

run torch flame along the back side (solder side) of board slowly and steadily (try to heat the board up gradualy at first, to avoid stressing the part).

at the same time vibrate the hell out of the board. my jig has a motor with a cam attached to it that does this for me.

chips and components fall off the other side like mad. Even smt parts if you are carefull .

the JIG:



<| |> <- Hinge this end to base.
+-------------------:-|| <- ready rod file threads off one end
flat bar | | and weld a washer on the end so it will
o o turn in the rail but wont pull through
| | hole in the rail .Weld nut onto rail,
| | and nut onto end of the rod.
| PCB goes between |
| rails on 4 studs |
| |
o o <- studs hold pcb in place when being
| | vibrated (just a screw or something).
| |
+-------------------:-|| <- same as above. tighen two nuts and
| | pcb gets squeezed between rails.
|====================|
#######__O <- motor with cam.
#######

Hope this can help, it works ok for me.

1172. VHF to UHF - Best design ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-16 08:41:21 UTC
From: elendir@enst.fr
Message-ID: <2r7bjh$mq2@cismsun.univ-lyon1.fr>
Source record: 117811

Hello again,

I�m still involved in that multimode VHF/UHF TRX. To actually translate
VHF to UHF, I thought about a threefold frequency multiplier in series with
the VCO. Then mixing. So, if you don�t activate the x3, you get VHF and if
you do you get UHF.
But there is also the solution of generating VHF anyway then translating
with a ~290 MHz carrier to get UHF. (Simplifies filtering)

Which solution, according to you, is best ?

Also, is it possible to find sharp filters for the 2 m and 70 cm band ?

Thanks and 73,
Vince - F1RCS.

Subject: Somebody named Loomis invented radio?
Date: 1 May 1994 02:01:51 GMT
Organization: University of Illinois at Urbana

I read something recently that a man named Loomis might have
"invented" radio in the late 1800's before Marconi & Hertz et al.

This might be an ancestor of the person for whom the University of
Illinois physics department "Loomis Lab" is named.

Does anybody else know more about this?

1176. post QRP-Digest here?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-16 19:51:34 UTC
From: bruce@Think.COM
Message-ID: <2r8is6INNfm@early-bird.think.com>
Source record: 117814

As some of you know, I administer an Internet mailing list devoted to QRP. Since there is much cross-interest among the QRP crowd and homebrewers, someone suggested that I post the daily digests from the QRP list to this group (one message each night) on an experimental basis.

Note that I am *not* planning to feed the messages from this newsgroup into the QRP list; if you want to reply to a topic on the list, you will have to mail to the specific recipient or to the mailing list as a whole.

If you have strong feelings one way or another, please let me know in private mail.

If you just want to join the QRP mailing list, send a "subscribe qrp" or "subscribe qrp-digest" message to majordomo@think.com, not to me personally!!

I need to gather some info on building an antenna for short wave reception? Please excuse my ignorance, I am very new at this. Someone told me that All I need to do is connect a very long thin wire from an adjacent tree to the house and one from the ground and connect them into the adapter that goes into the external antenna plug. I have some questions:

1) How long should this wire be? Is it somehow related to the frequencies that I am interested in? What if I am interested in more than one?

2) should the wire be shilded or unshielded?

3) what should be the gauge of the wire? The thicker the better?

4) should the wire be the meshed type or a single thread?

Yes, there are - I'm using an Australian 8051 cross compiler (DOS hosted)
now (from a company called HiTech in Queensland - hitech@hitech.com.au).

Keep a lookout for the 8051 faq, which is posted monthly, or if you can't
wait, drop me a line and I'll mail you a copy of the April release.

hi, mitch wa4osr here in mobile, alabama...

my sharp pc-6200 was dropped and the lcd display
was damaged... upon taking the display apart, one
of the surface mount column drivers was cracked...
rendering the display unusable... therefore,
i am in desperate need of the lcd display panel...
the part numbers on the display panel are LM64N671
and 90D13145W ... both numbers are on the panel...
my pc-6200 is actually a pc-6220, which
i think indicates that it has a 20 mb hard drive...

i bought the pc-6220 used with absolutely *NO* docs...
it has the 2400 baud internal modem... i need *ANY*
info, but especially would appreciate a copy of the
owner/operator manual... i will gladly pay for
copies/postage...

if anyone can help with a source of the lcd panel or
with the docs please email me or call me collect
at the below numbers...

thanks for any help/leads...

Dr. Loomis was a dentist. If I remember correctly, he used a non-powered system where he simply connected his "transmitting" antennae to ground via a telegraph key. I assume that at all time a very small potential difference existed between the antennae and ground, when the key opened and closed, a small current flowed and excited the antennae at its resonant frequency. I'm not sure what he used as a detector, but it did work.

I read about this in one of the ham magazines over ten years ago, so I can't remember all the details.

Often you can see this effect with a TV set. Connect a set of rabbit ears to a TV set and tune in a weak station. One that is right on the verge of snow, but not too bad. Then cut a metal rod to about 1/4 wave at the appropriate frequency. Hold this rod in the plane of the rabbit ears (same polarization) and tap the rod with a metal screwdriver. Many times you can get "sparkles" in the picture by doing this.

Ben,

I will need to acquire a portable VHF data radio and packet connector before I can do anything. If you know of anyone that is selling either of these, please tell them to send me a message of what they are selling and how much it is selling for. I will try to buy from people that Joe Thiel would be willing to buy from.

I am a programmer for the Health Department. I probably will not have any problems connecting the equipment together, and to my computer. I have already assembled (built it) and configured (setup CMOS, etc.) my IBM 386DX. I think the only problem that I will encounter will be in configuring software between each piece so that I can connect to the internet. I will be able to get all of the assistance I need from Joe. If I need any more assistance, I will send you a message. I have an account on internet via the Health department. Do you mind if people access A. Farm via the internet? Can I access A. Farm Via the internet?--I can ask Joe, but since I am writing this message, I will just ask you.

Do you want scanned color images placed on your BBS? These images do take up room, even in the compressed and 16color format. I have a scanner, and I can scan in a image for you. As for programs etc for uploading, What are you interested in. I might have something you would want, or can generate something that does the same thing. I will be restricted by my work demands and I cannot give you anything that would look like it could have come from my work (even if I created the code).

Well, I must get some work done. I also need to study for the Amateur Radio Exam.
Cynthia

Loomis took advantage of the roughly 300 volts/meter potential in the atmosphere to activate his transmitter. The current flow is small, except during thunderstorms, but it was sufficient to generate a detectable signal at a distance in the days before widespread use of electricity.

Nathan B. Stubblefield's work was much further advanced. He sent *voice* signals over distances greater than 30 miles before Marconi et al sent spark signals. His system was powered by batteries and apparently worked on the principle of sheet conductance. (He was very secretive about the exact details.) He conducted a demonstration for Congress where he communicated by voice with a ship in the Potomac from the shore. His was the first "underground" radio station.

And of course there was Tesla. He had radio controlled boats operating in the lake of Central Park in one demonstration well before Marconi generated his first sparks. Tesla was fasinated by resonance phenomina.

1188. Digital Delay Circuit Ideas?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-18 13:31:51 UTC
From: jra@lawdept.daytonOH.ncr.com
Message-ID: <jra.126.00088822@lawdept.daytonOH.ncr.com>
Source record: 117726
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc

I'm designing a clock to be driven by my local frequency standard. My goal is to be able to set the second mark to better than 1 millisecond (and I hope eventually much better than that).

To do this, I need to build a variable delay that I can use to slew the seconds marker. Actually, I'll need a couple of delays, starting at a higher frequency for fine adjustment, and finally running at a lower one for course adjust. Obviously, for stability reasons I want to do this digitally and not with some sort of analog delay.

Any suggestions on CMOS devices (probably a presettable counter?) that would work well here? The larger the count range in a single chip, the better.

Thanks...

John AG9V

You might try the "SHV" or "MHV" series of connectors. They look a
little like BNC, but are rated at 5000 volts peak, 5 amps, to 50MHz.
They are for coaxial cable, which is a decent idea at high voltages
anyway: I've always felt a little more comfortable with a grounded
barrier between me and the high voltage. But the connectors in this
series are pricey. Newark, for example, lists them.

There's also a fairly standard connector used on HeNe lasers, but it
may not be rated for the current you want to use. Try laser supply
places (Meredith in Phoenix??) for these.

Is Millen still in business??

The 8XC750 is in the same class as a MicroChip PIC (like a 16C55)
except that it can run at 40Mhz, has a somewhat more complex
instruction set, and more i/o pins in the skinny DIP package.

Beware: Mhz are not directly comparable. Those "more complex instructions"
take a lot more cycles to execute as well. Most instructions take 12 clock
periods, and a fair number take 24. So a 12Mhz executes most instructions
in one microsecond, while a 20Mhz PIC executes most instructions in 200nS.

David Billsbrough (kc4zvw@stardust.oau.org) wrote:
: There is a Philips Dream Machine 8XC750 design contest.

I got my DS-750 toolkit (I know, another in a series of nanocomputers)
and was very favorably impressed. The 8XC750 is in the same class as
a MicroChip PIC (like a 16C55) except that it can run at 40Mhz, has
a somewhat more complex instruction set, and more i/o pins in the
skinny DIP package. I also got the MicroChip kit when they were
doing their design contest, the Phillips one beats that by quite a
bit.

The Phillips DS-750 kit includes:
(2) 8xC752 samples (used to emulate a 8xC750)
(1) 8xC750 sample
(1) serial cable
(1) Wall bug type power supply
(1) Assembler/Simulator/Debugger package (MS DOS)
(1) Programmer/Emulator - Programs 750/1/2 parts, emulates 750
parts.
(1) Manual (copyright March 1994!)
Nice plastic binder/box for storage.
Phillips 8x51 series databook
Phillips Application Notes

Unlike the PICSTART-16B which contained the programmer, no emulator, no
serial cable, no powersupply, and no box to keep it in.

Anyway, my suggestion for anyone who is playing around with small dedicated
processors is to not miss this deal.

From: david@lambton.on.ca
Message-ID: <Cq0MI2.5up@lambton.on.ca>
Source record: 117731

We are are thinking of upgrading our 2m repeater to include some
remote recievers, linked back on 70cm and selected through a
Doug Hall Electronics voter.

What is the general wisom as to sources of link recievers/transmitters
what to use for remote (cross band) repeaters, expected ranges,
power level, etc?

I think that a Kenwood 732 would make a cheap remote site, if it
was set to low power it could probably handle the duty cycle.
A small brick could boost the power.

We still need recomendations on recievers that have fixed audio
and COS outputs, and are rugged enough for this use. Synthisized (sp?)
would be nice.

Has any one tryed this? Ideas?

I'd be real concerned about the receiver performance on the 732.
It's not all that good for general mobile use and on a radio
site, it would be even worse (unless its way out in the boonies
where this is zero RF).

Page 58 of the manual says:
Caution This equipment can be extremely susceptible to lightning
strike damage or intermodulation distortion if it is
operated on mountain top locations.

I guess you could protect it with bandpass cavities or helical filters.

>What is the general wisom as to sources of link recievers/transmitters
>what to use for remote (cross band) repeaters, expected ranges,
>power level, etc?

Motorola and GE are always good choices. Micors and Exec IIs can be split with a VHF receiver and a UHF transmitter in one case. This makes a nice bulletproof remote. Or you can use purpose designed link equipment from Neulink or Grainger. The link should be at the lowest power that gives adequate fade margin. Beams are highly recomended. Use of microwave links instead of 70 cm is highly recomended since the link segment of 70 cm is filling beyond capacity in many areas. Grainger 900 MHz link transmitters and receivers are good, or you can go higher with equipment from Linkhurt, M/AComm, or Motorola.

>I think that a Kenwood 732 would make a cheap remote site, if it
>was set to low power it could probably handle the duty cycle.
>A small brick could boost the power.

Horrible choice. The intermod at a good high site will drive this radio crazy. It's transmitter is also dirty enough to generate complaints from other site users. About the only amateur grade equipment that's usable at a high site is the Icom 900/901 band modules, and they aren't really great.

>We still need recomendations on recievers that have fixed audio
>and COS outputs, and are rugged enough for this use. Synthisized (sp?)
>would be nice.

Synthesized would be bad. You want crystal controlled receivers with at minimum TCXOs, and preferably ovens. Stability is critical, and the cleaner LO spectrum of the crystal rigs will also help reject other crud on the site. Watkins Johnson made some great shelf mount single channel receivers for this purpose, but you could press Micor or Exec II receiver strips into service. If you use the split setup I suggested at the remote sites, you'll already have the UHF receivers left over from those. You can put two receiver strips in a single case. COR and fixed audio can be obtained from these receivers in exactly the same way you would if you were using them for ordinary repeater service. Probably 90% of ham repeaters use either the Micor or Exec II. There's a reason for that.

billw@glare.cisco.com (William) writes:

] The 8XC750 is in the same class as a MicroChip PIC (like a 16C55)
] except that it can run at 40Mhz, has a somewhat more complex
] instruction set, and more i/o pins in the skinny DIP package.

]Beware: Mhz are not directly comparable. Those "more complex instructions"
]take a lot more cycles to execute as well. Most instructions take 12 clock
]periods, and a fair number take 24. So a 12Mhz executes most instructions
]in one microsecond, while a 20Mhz PIC executes most instructions in 200nS.

'Tis true. Perhaps Philips should follow Dallas' lead and reduce the number of clock cycles per machine cycle, instead of just pushing the clock and internals to the limit. (Maybe that's why they made it run up to 40MHz, to make it competitive.)

Nevertheless, I'm glad I've got a skinny-dip 8031-core chip to play with. I'm just miffed that it doesn't have a UART, since just about everything I build talks to my PC via RS-232, and so I'm stuck with low speed and complicated, program space-hogging comm routines.

Get an old copy of the "IC Master" published by Hearst Business Publishing for basic information on virtually any IC chip. These books are about $170 new, and are published annually. You should be able to get a five-year-old copy for next to nothing.

Hi,

i just built a 2-transistor, .2 Watt transistor.
I can get pretty good range with it (approx 250 metres) with a 'bad'
set-up ,ie not covered, poor antenna.

I'm looking to build a bigger, more powerful model, and also make
an efficient antenna.

Can anyone give me any information on doing this?
Also can anyone reccomend any TEXTS are transmittor construction,
esp one with circuit diagrams.....

Thanks.

Si.

Reginald Aubrey Fessenden, a Canadian, actually sent the first voice message
without the help of wires on December 23, 1900 from Cobb Island in the Potomac
river. He also improved Marconi's wireless system, made the first radio
broadcast, and invented sonar. An article appeared in Equinox magazine several
years ago that detailed Fessenden's achievements.

First, I didn't mean to "compare" Mhz. I agree with everyone that they aren't comparable. However I stick by my original statement that the Microchip "PIC" and the 8xC750 are in the same "class". (This is a tautology since I also get to define the term "class" :-)

A very good idea that I hope Phillips picks up on, I have the impression though that they got this core loaded up into their ASIC library and now they are whipping out chips right and left. Its much lower risk to stick with a working core.

Someone else just posted the serial I/O routines for the 8031 and they were pretty small. (Dave Dunfield I believe). I don't mind doing bit-banger routines, but I do mind (on the PIC at least) that I really have to use clever programming to get asynchronous I/O.

Dallas seems to be the company into unique packaging variations. They say
they're soon going to put onboard memory on their hi-speed 80c320, I suspect
it'll be NVRAM. Maybe they'll forfeit some leads and stick a version in a
skinny dip package. 2K of program memory, a UART & serial programming, and
18-24 pins would be nice.

I posted these in the new DS-750 mailing list. Here they are for
general consumption. They occupy 47 bytes of code space.

```
*
* "Bit-bang" serial I/O functions for the 8051.
*
* These routines transmit and receive serial data using two general
* I/O pins, in 8 bit, No parity, 1 stop bit format. They are useful
* for performing serial I/O on 8051 derivatives not having an
* internal UART, or for implementing a second serial channel.
*
* Dave Dunfield - May 17, 1994
*
* NOTE that R0 and R1 are used by the functions. You may wish to
* add PUSH/POP instructions to save/restore these registers.
TXD set P1.0 Transmit on this pin
RXD set P1.1 Receive on this pin
* The serial baud rate is determined by the processor crystal, and
* this constant which is calculated as: (((crystal/baud)/12) - 5) / 2
BITTIM EQU 45 (((11059200/9600)/12) - 5) / 2
*
* Transmit character in A via TXD line
*
putc CLR TXD Drop line for start bit
MOV R0,#BITTIM Wait full bit-time
DJNZ R0,* For START bit
MOV R1,#8 Send 8 bits
putc1 RRC A Move next bit into carry
MOV TXD,C Write next bit
MOV R0,#BITTIM Wait full bit-time
DJNZ R0,* For DATA bit
DJNZ R1,putc1 write 8 bits
SETB TXD Set line high
RRC A Restore ACC contents
MOV R0,#BITTIM Wait full bit-time
DJNZ R0,* For STOP bit
RET
*
* Receive a character from the RXD line and return in A
*
getc JB RXD,* Wait for start bit
```

```
MOV R0,#BITTIM/2 Wait 1/2 bit-time
DJNZ R0,* To sample in middle
JB RXD,getc Insure valid
MOV R1,#8 Read 8 bits
getc1 MOV R0,#BITTIM Wait full bit-time
DJNZ R0,* For DATA bit
MOV C,RXD Read bit
RRC A Shift it into ACC

1209. 40m Transmitter or VFO project??- any suggestions?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-20 05:50:27 UTC
From: n9rzc@uiuc.edu
Message-ID: <n9rzc-200594004612@ruger-13.slip.uiuc.edu>
Source record: 117746

Hello all,

I recently purchased an old boat anchor which is an upgrade from an older boat anchor, but most importantly, it was cheap and it works well. I am planning on upgrading to general this summer and am looking for a nice 40m project (or if you really really prefer another band, I'll take suggestions about bands also). I was thinking along the lines of a QRP cw transmitter that would allow me to make a little set-up for myself. I have a small transmitter (only transistor and such) already in mind that was origionally x-tal stuck, and I figure I could pop in a vfo instead of the x-tal in the project if I wanted, so I'll take suggestions on vfo projects also. I recently did a small 2m kit, and I will be much happier in the lower freq's :) (lead length and such).

In anycase, I'm in your hands, mold me and shape me into something nice!!!

TNX A TON (that's about what this thing weighs ;)

Je vois que tu as comme moi une installation QRP. Je ne suis pas sur a
100 %, mais la propag en E-spo est quand meme tres sportive, surtout sur
2 metres. A mon avis, avec un petit portable ca n est guere possible. La
plupart des contacts en 2 metres BLU se font en tropo ou en meteor scatter.
Les ouvertures en E-spo sont rarissimes. En plus, la BLU etant plus efficace
que la FM va evidemment plus loin. Sur UHF, il n y a plus de E-spo, que de la
tropo - sauf condition vraiment anormale.
Quant a la prevision de la spo, comme son nom l indique, elle est justement
imprevisible. Ce sont des paquets ionises plus fortement qui se forment et se
disloquent on ne sait pas trop comment. Le mieux est de rester a l ecoute !!!
Mais la E-spo, c est grand sur la bande des 6 metres !!!! :-)

73 QRO !

Thanks; a very nice summary. The site where these experiments took place is near my home, in the Virginia mountains west of Washington, DC; there's a historical marker there. His "antennas" were very long vertical wires supported by kites. Loomis thought he was somehow tapping into a flow of aetheric energy moving through the sky. What he was really doing was electromagnetic induction, powered by the atmospheric potential difference between ground level and the top of his skywire some hundreds of feet up. A true pioneer, he was right for all the wrong reasons.

(Allen Hall asked about qrp cw transmitters as a remedy to
boatanchors :)})

I've built the Ramsey 40 meter receiver and transmitter.
Although the transmitter works OK, the receiver is less
satisfactory. Recently I received an NN1G 40-40 QRP kit from the
New England QRP Club which I'm currently building. They have a
new round of these being prepared, so I'll give you the
announcement:

From: mvjf@mvubr.att.com (James M Fitton +1 508 960 2577)
Date: 19 May 94 17:26:00 GMT
Subject: 40/40 kits

Second batch of 40/40 kits :

QRP-New England Club reports that 38 orders for the
second batch of club 40/40 (40m and 30m) transceiver
kits have been received.

All parts for the second batch have been ordered and
kits should still be available in June.

To receive a file on kits and NE club, e-mail your
request to mvjf@mvubr.att.com.

You may also wish to get onto the mailing list for QRP that I got
this information from. Send a message to :

Majordomo@Think.com

To subscribe to the daily message digest on QRP send this

Kenneth...Judging from your message, it appears that you are coming
from the Pirate Radio group......if so you are posting this message
in an Amateur Radio group. We are licensed amateur radio operators
and we do not think kindly of unlicensed operations. There is more to
building a radio transmitter that just putting the parts together and
trying to get something on the air. A poorly built transmitter could
transmit on more than the intended frequency at one time and you
could unknowingly create interference.

If you are interested in becoming a legally licensed ham operator,
let me know and I can point you in the right direction.

What was quirky was the TMS2716 : it used different programming voltages
than everyone else's 2716. The TMS2516 was TI's version that used the
same voltages as everyone else (so I guess its quirk was that it was
numbered differently).

You don't give enough detail about your circuit to make a definite choice, but I would be extremely inclined to use a low-end microcontroller here. Depending on the device you select, you should easily be able to set up a selectable delay accurate to anywhere from one microsecond to .1 millisecond.

For that matter, why not do the whole thing in a microcontroller?

Rule of thumb for a dipole antenna: element length (in feet) = 234 divided
by the frequency in MHz.

1224. FCC licensing delays

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-22 00:01:00 UTC
From: darryl.linkow@ledge.com
Message-ID: <cf.889.437.0N2EEB84@ledge.com>
Source record: 117765

Hello all! I have now been waiting for 7 weeks for my first
license to arrive in the mail. Having read all the horror stories
on the nets regarding waiting times, I decided to call the FCC in
Gettysburg and find out what the REAL problem is myself. I spoke
to a very nice woman who told me that it is now taking from 12 to
14 weeks to process application forms because there is only ONE PERSON
keying in the information to the computer. Also, she said that
the "new computer" that people have talked about on the nets is not
online yet. (Hmm...it only took me a couple of hours to set up my
latest 486 box!). At any rate, this ONE PERSON evidently has
thousands of licenses to process. The woman told me that she had
not heard of any offers from the ARRL regarding local volunteers in
the Gettysburg area coming in to help out with the backlog and
enter data into the computer. I told her that since we have
volunteers doing license testing, at no charge to the Federal
government via the VEC program, it seems that we could have
volunteer personnel to perform data entry! She also told me that
the Gettysburg office has requested additional help several times from the
Managing Director of the FCC in Washington, D.C., but the man
refuses to give them any more employees, for even a short period of
time, to clear up the backlog of license applications. I have
called my local Congressman, Representative Anthony Beilenson, and
told one of his staff about the problem. I asked if the
Congressman could contact the Managing Director and ask for some
additional staffing in Gettysburg, at least on a temporary basis,
to get the backlog of amateur radio applications (Form 610)
processed. Perhaps if everyone told their respective Congressman
about the problem, we could get some help! Here is the name,
address, and phone number of the FCC Managing Director who will not
let Gettysburg have any additional people to help get rid of the
backlog: Andrew Fishel
Managing Director
FCC
1919 M Street, N.W.
Washington, DC
(202) 632-6390
Just as an aside, I decided to get my amateur license because of
the problems associated with the January 17 earthquake here. The
American Red Cross had a severe shortage of qualified amateur radio
operators to handle emergency traffic after the earthquake. So, I
decided, as a citizen of the community, that I would get my
license, so that I might get involved in disaster communications,
and be ready to assist, if needed. But, as of right now, I can not
participate in any emergency networks until my license arrives!!

Also, I am routing a copy of the above information to President Clinton and Vice President Gore. I understand that Vice President Gore is very interested in information processing and bottlenecks in those areas of the government that are having problems processing data.

I am open to discussing this with anyone on the net, but if you want to work for the improvement of this problem, please call or write to Mr. Fishel and your elected federal government officials in Congress and The White House.
Sincerely,
Darryl Linkow (no callsign after 7 weeks and don't expect to see one for another 5 to 7 weeks!)

More to the point, and not wanting to seem sanctimonious, we don't
want to risk *our* licenses by incurring any legal liability for what
you are doing. So all you'll get here is references to a few standard
handbooks. We're not snobbish; but, as license holders, we have more
than the usual reason to steer clear of anything illegal.

At least it isn't like The Bad Old Days, when the _exams_ were only once every three months. :-)

The FCC took 12 weeks to get me my last license. They have in recent memory been as fast as 7 weeks, but that didn't last long. It takes time, and one should simply accept that and be patient. Use the time to buy a copy of the ARRL Handbook or Operating Guide and read it, or buy a receiver and start working on your Morse Code. Just think of the boasting power you will have if you can upgrade to General or Advanced before your first license arrives!

In other words, yes, it's a bother to wait, but don't sweat it. The wait is not known to be fatal. If you want to get involved in ham radio Right Now (and what new ham doesn't want that?), buy books and read them and buy a receiver and listen. You'll learn a lot and be much more ready to start participating when that license arrives.

Because this has zilch to do with homebrewing, please send any followups to rec.radio.amateur.misc. Thanks.

Hi ya Si,

my local electronic junk shop sell contruction kits conplete with PCB and components.They do a 25 Watt 2 Transistor module and a lower 15 Watt version.
I dont know what frequency tese are on. I know they are FM but unsure if they are Narrow or Wide band... Net mail me or E mail me and I will try and find out more info for you. Thats if this is what you are looking for...

Keep your head down.
All the best

I'm re-entering home-brewing after a long absence. My skills include all the oldfashioned stuff you don't much need anymore. Like laying out aluminum panels, wiring kilovolt circuits so they don't kill you, even winding tank coils on octal-plug forms. Even so, I can actually etch a circuit board and get the circuit to work. But one item has me stumped: How does the average kitchen-sink tinkerer get the two sides of these complex, double-sided digital boards to register. Close is clearly not enough with these boards...looks like you need to be in register to +- .01 inches. One thing has occurred to me. I could try using the Xerox-transfer, iron-on patterns, etch one side, then drill it and register with holes cut into the pattern for the other side. Guess that would work, but it seems like a LOT of work.

So what simple operation am I missing? And if this is already in a FAQ somewhere, please accept my appology in advance, and point me to it.

Thanks!

G = >We are are thinking of upgrading our 2m repeater to include some
G = >remote recievers, linked back on 70cm and selected through a
G = >Doug Hall Electronics voter.

Why not just put the 2m remote at the same site?

G = >What is the general wisom as to sources of link recievers/transmitters
G = >what to use for remote (cross band) repeaters, expected ranges,
G = >power level, etc?

G = >I think that a Kenwood 732 would make a cheap remote site, if it
G = >was set to low power it could probably handle the duty cycle.
G = >A small brick could boost the power.
G =
G = Horrible choice. The intermod at a good high site will drive this
G = radio crazy. It's transmitter is also dirty enough to generate
G = complaints from other site users. About the only amateur grade
G = equipment that's usable at a high site is the Icom 900/901 band
G = modules, and they aren't really great.

I concur. I have three friends that had the '732. The radio is a piece
of rubbish. The receiver is one of the weakest I've ever had the dis-
pleasure of using. It sucks in noise and gets saturated so badly in this
city that it often becomes unusable. One of my friends had the RX front-end
repaired twice before the front panel melted completely and has become
unrepairable. Many of the features are poorly engineered or simply don't
work.

G = Synthesized would be bad. You want crystal controlled receivers with
G = at minimum TCXOs, and preferably ovens. Stability is critical, and
G = the cleaner LO spectrum of the crystal rigs will also help reject
G = other crud on the site.

I wonder if the original poster meant a frequency-agile-remote-transceiver?

I (Kenneth Seymour) am not the person requesting transmitter information.
I was responding to a post from siwasaki@unix1.tcd.ie. Had I looked
more closely at the original post, I would have realized that this
was not a radio amateur with a ligitamate request on how to make legal
transmitters. When I posted I did not notice the cross post to a
pirate radio group. Nor did I notice that this person goes by the
name "Pleasure Death".

I appreciate the offer of assistance, but I already hold licence KN6QC.
Thanks anyway.

Just to clarify I AM NOT THE PERSON WHO ASKED ABOUT FM TRANSMITTERS.

What you do is have registration bullseyes on at least the four corners
of both patterns, drill holes through the board based on one pattern's
bullseyes (often the holes that will end up as the board mounting holes),
and register the other pattern on those holes. Now expose both sides, and
etch. Yes it is a pain to do double sided boards. For real pain, try doing
multi-layer boards.

Maybe you don't. There are some things that are beyond kitchen-sink
tinkerers--building GaAs MMICs, for instance. It is entirely possible
that the traces on a board will be too thin and require too much precision
to easily fabricate at home. Interestingly enough, the digital people have
pushed board houses to the point where getting "precision" etching for
microwave microstrip work isn't really a problem anymore.

However, you might consider wire-wrapping such a board. Many people have
had good results with this, even with clock speeds in excess of 20 MHz.
Or, go ahead and buy the board...

I hesitate to post to this group anymore - I seem to get responses indicating that I should know all the answers since I have an extra class license. Anyway:

Anybody ever made any sort of measuring device for measuring the back pressure in a cooling system for a transmitting tube? I have seen references to things like so many cubic feet of air flow. Or .6 inches of backpressure. Or does everyone just make sure they are running a blower that is over-rated just to be safe? I'd prefer to do it right, since the bigger the blower, the more noise present in the shack. Unless I put the blower in a different room! If this is the sort of thing that interests others, you might post your comments here rather than direct to me. Thanks....

1235. Need help on inductor winding

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-23 15:26:21 UTC
From: white@ccsua.ctstateu.edu
Message-ID: <1994May23.102621.1@ccsua.ctstateu.edu>
Source record: 117673

I'm building the RadioKit QRP-20 kit. The manual calls for inductors
with "2-T links"..... what does that mean? Does it mean a 2-turn
secondary? Thanks, and if anyone has info on winding inductors (esp.
the oddball subminiature inductor for the 7MHz Optimized Transceiver),
I would appreciate a lead on where to find it.

Mahon Loomis - yup!

Didn't exactly invent radio, but he did experiment with atmospheric
communications. Seems he flew two kites with wire for leads. In one lead
was a telegraph key and in the other a primitive galvanometer.
Keying one circuit gave a reading in the other, which was located several
miles away.

That's serious qrp work.

This is not my line, and so comes under the category of ANY advice...
2
You need to current bias as there are 3 places on the v-i
curve for the tunnel voltage. So find the tunnel current first (from
specs), and you don't get any choice about the voltage.

1241. Modification of walkie talkies..

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-23 23:35:59 UTC
From: sebelt01@starbase.spd.louisville.edu
Message-ID: <2rrekv$90c@hermes.louisville.edu>
Source record: 117681

I want to modify a pair of (cheap) walkie talkies to have greater range. I have three things in mind:

1 - Improve the antenna: 49.860 / 468 = 9.4 ft. Will a 9.4 ft length of wire do the trick? What gauge is _best_?

2 - Get rid of some resistors. It seems that there is a resistor right between a very small coil and the antenna. I'm not sure of it's purpose (does it just reduce the output power, or limit interference, or protect something in the transceiver? The resistor is labeled L2, with the coil before it labeled L1. (Which makes me thing it has somethign to do with tuning or interference).. If I remove this will my signal become stronger? (where I'm using these interference will be virtually no problem).

3 - Add an amplifier. How hard is it to amplify the signal? Is it just a matter of adding on a resistor, or is such a circuit more comples. Again, I'm not too worried about causing interference where these transceivers will be used, but I need to make them as powerful as possible.

Thanks for any help/suggestions/whatever. Please respond by mail if at all possible, I will post a summary in the form of a how-to, if I can get this to work.

: tuner? (aside from external components) any help would be appreciated.

Sounds like it would be more trouble than it's worth. You would have to unsolder the bandswitch and replace it with one with an extra switch position. Then you'd have to add a 160 meter tank coil. The only thing that would likely fit would be a high-power powdered-iron toroid. The tuning capacitors would likely not have enough range -- you would have to add switchable fixed capacitance in parallel with both of them.

It would probably be easier to build a separate 160 meter tuner and use the MN2000 to switch it in as appropriate!

That's a bad idea. Read on to see why.

> 1 - Improve the antenna: 49.860 / 468 = 9.4 ft. Will a 9.4 ft length of wire
> do the trick? What gauge is _best_?

It could conceivably help, but you need to use the right formula for the
antenna design and connect it correctly to the radio. The radio may be
designed for the antenna it is using and may function incorrectly with
other antennas.

> 2 - Get rid of some resistors.

Not all that looks like a resistor is one. With a name like L2, that
"resistor" is an inductor. It is there to reduce interference, to match
the transmitting circuitry to the antenna, or both. Don't remove it.

> If I remove this will my signal become stronger? (where I'm using these
> interference will be virtually no problem).

Removing L2 will not improve your signal in any perceptible way. If it
is there for antenna matching, removing it will make your signal worse!

The interference you can cause will be a problem. Plopping a spurious
signal into the FM broadcast band, the business band, or a TV channel is
uncouth. Putting it into the aircraft band could cause safety problems.
Worse, you can't know whether you are causing interference without test
equipment like a spectrum analyzer.

> 3 - Add an amplifier. How hard is it to amplify the signal? Is it just a
> matter of adding on a resistor, or is such a circuit more comples.

An amplifier requires more than a resistor.

If you want better range, I suggest a CB in handheld or mobile form.
That will give you 4 watts output in near-line-of-sight communications.
For better than that, get a ham radio license. The no-code license is
not too hard to get and opens a wide range of communications.

What are you trying to do with the radios, anyway?

See recent issues of both Computer Craft and Dr Dobb's Journal for articles
on how to use serial-output ADCs. The outputs are not RS-232, and it's
easier to attach them to a parallel port than a serial port (even though
the bits are sent serially).

Eh? For a given _current_ there can be up to three possible _voltages_.
But for a given _voltage_ there is only one _current_. So if you want
it stable, bias it with a _voltage_. Use a very low impedance source.
It must be low impedance at all frequencies that the diode is likely to
oscillate at, or you may have trouble in the negative resistance region.

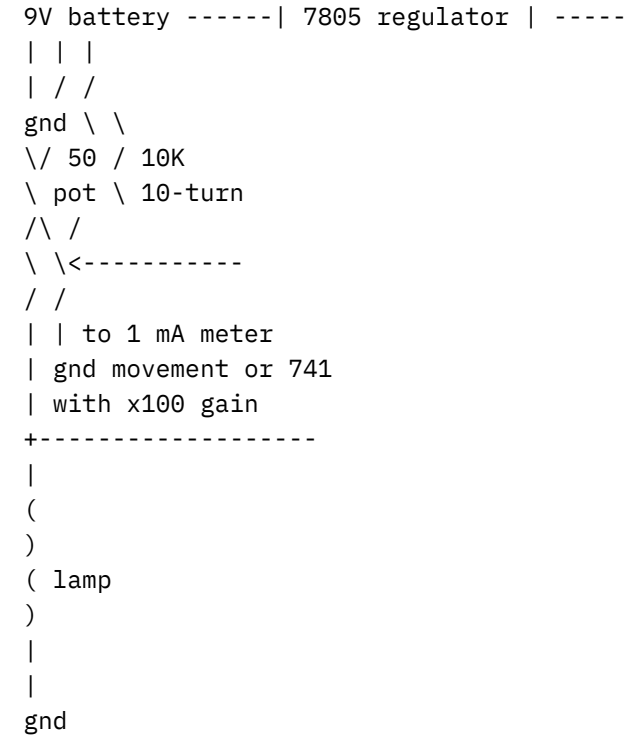
What you need is a hot-wire anemometer!



The lamp is a 12V automotive bulb, with the envelope broken and
the filament exposed to air. Before breaking the bulb, set the
50 ohm pot so that the lamp just barely glows, then back off
slightly until it no longer glows at all. Then set the 10K pot for
zero output level. Now break the envelope.

You will see a significant DC offset on the output with the envelope
broken, because the filament is exposed to air which cools it considerably,
reducing its resistance. The greater the airflow, the less resistance, and
the greater the meter reading. You will need a couple of fans with known
air speed rates to calibrate it.

This will only measure velocity, not volume, so you need to multiply by
the area of the cross-section of the chamber which you've got the thing in

in order to get a flow rate.

For better accuracy, you can replace the 10K resistor with two fixed resistors and a pot so that the varies along a much smaller range. I give the above as an example that works and is an easy proof of concept model.

This is not as sensitive to ambient temperature as you might expect, either. If you are worried about that, you can run the filament hotter, but you will have a much shorter lifetime of the lamp.

The standard way to do it is with a plastic tube filled with water. Seal one end of the tube inside the chassis and fasten the other end somewhere in the outside air. Turn on the blower and note how much the water level changes.

However, the real thing you are concerned about is not the air pressure, but the temperature of the tube. The base seals are generally the critical components. A good inexpensive way to measure the temp is to use temperature-sensitive paint (Tempilac brand, for example). The paint changes color when it reaches its critical temperature. Buy using several different paints of different critical temperatures, you can determine the maximum seal temperature.

Check out the Postage Stamp board. It's a little RISC engine programmed with
a BASIC interpreter. There's some good stuff in this month's Nuts & Volts,
and the Parallax stuff us available from DigiKey.

The processor boards are 1 inch by 2 inches. There are 8 I/O pins that can
be used for several purposes, including serial I/O. Processor boards are
$39 from digikey (power is a 9V battery, or build a power source), and
a development kit is somewhere around $130, including on processor board.

I'm planning on taking a closer look at these, as they would appear to be
a VERY cheap way to implement a lot of stuff...

You can make a simple "U-tube" manometer with plastic tubing and water
and measure "inches of water" pressure/vacuum that way.

You could do the A/D conversion in software on the PC. Dual-slope integration is accurate and requires as little as one digital output and one digital input. DTR, DSR, RTS, and CTS on the serial port could serve for the I/O.

At 1 Hz samples, it's not going to put much of a demand on the CPU. Accurate timing is a must, though, so you need either a high-resolution timer or the ability to turn off interrupts for long enough to do software timing.

>in a cooling system for a transmitting tube?

Eimac frequently shows a manometer for measuring backpressure. A manometer is similar to a barometer in that it is a u-shaped tube of fluid, usually water, with the "free" end open to atmosphere and the "business" end attached to the pressurized compartment.
The tube is only partially filled with water, to fill in the "U". Not so much to spill into the pressurized compartment!
With the compartment pressurized, the difference in the levels of the water in the tube are a measure of the backpressure in the compartment. The exact calculation of pressure depends on the cross-sectional area of the tube and (i guess) the barometric pressure at the time of measurement.
I can send you some copies of Eimac application notes if you're interested.

There are many ways to measure flow, but the approach generally taken
with air system sockets of known flow restriction is to measure back
pressure. That can be easily done with a device called a manometer.
You can make one simply from a piece of clear flexible plastic tubing,
a ruler, and some water. Form a U shaped tube partially filled with
water. Leave one end of the tube open to atmosphere and run a flexible
tube from the other end to a sampling point in the input compartment
of the amplifier. Measure the difference in height of the water in
the two legs of the tube. This is the overpressure in the input compartment.
Now move the probe to the output compartment and measure again. The
difference between the two readings is the pressure drop through the
air system socket. It should not exceed manufacturer recomendations for
the tube in use. (Back pressure is given in inches of water for air
system sockets.)

Measuring air velocity is another method of estimating CFM, but is
generally less reliable. A cup anemometer could be used, but it
would give inaccurate results for flows near the edges of the duct.
However, a vane system is often used strictly for alarm purposes.
This is just a paddle placed in the airstream such that the air
supports it's weight preventing it from closing a microswitch. If
flow drops enough, the weight of the vane closes the switch and
shuts down the transmitter. Alternately, the flow could be used
to keep the microswitch closed and loss of flow allowing the vane
to drop and allow the switch to open. Optical sensing of vane
position can also be used. If your amplifier needs forced air
cooling, some sort of flow based sensor should be used to protect
the system in the event of air system failures.

What you are really interested in, of course, is the temperature of
the tube seals. You can measure this directly in one of several ways.

Probably the easiest way is with a glass thermometer probe, but there are also thermal paints that can be used. These change color at a specific temperature. Paint a dab on the area to be measured, operate the equipment, and note the color change. Look up the color on the temperature conversion chart that comes with the paint, and there you are.

BTW, divorced blowers are a very good way to reduce noise in the operating area. Like a central vacuum cleaner system, they put the noisy blower a good distance away from the operator. Just remember to use large, low restriction, ducting to prevent excessive flow restriction. (4 inch dryer vent hose works well)

>be safe? I'd prefer to do it right, since the bigger the blower, the more

Measuring back pressure is fairly easy, using a manometer. A tube (> 4mm id) is bent in a U. Stich one end, into the pressurised volume, as right angles to the fan. Fill manometer with water, then measure height difference between sides. See the book "are and feeding of power grid tubes", by Eimac, which you can get from a Varian distributer.

PS

If you put an elastic band around tube anode, which holds a microswitch closed, then if the fan fails, band melts, microswitch opens ......

1259. Motorola GPS engine purchase information

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-25 18:21:22 UTC
From: bonomo@specxn.enet.dec.com
Message-ID: <1994May25.182122.12722@nntpd2.cxo.dec.com>
Source record: 117695

Greetings, one and all!

This message is ASCII text, formatted as <CR> at =<78 characters, tabs at +8.

Have finally received "everything" which I will obtain from Motorola and Trimble, and the order requests have dwindled to a minimum, I have attached the specifications and pricing below.

In a nutshell, the Motorola unit is better in every way, excepting three factors. The Trimble unit:

1) is about 1/8" smaller in width and height,
2) is about .6 ounce lighter,
3) consumes less power in standby, quoted as ~2uA nominal, versus the Motorola's stated maximum of 60uA.

Other than that, the Motorola VP Oncore engine is superior in all ways, including price. The recommendation, from my perspective, is to choose the Motorola unit, but your choice may vary. The above factors, in which the Trimble unit is superior, may be significant ones for you.

I have had requests from 375 individuals, from nine countries, for over 435 units. All this is, of course, based on a "$150" purchase price, which is not available.

Understanding this, it seems best if there is a "standard" configuration which is ordered, as the pricing given is for quantities of 100 and greater. If 100+ want the options, we'll order those, too. Remember, all prices are for 100+ units per item. In other words, if 25 units are wanted with the LNA option, the pricing for that LNA option will be be somewhat higher than the figure quoted below, and I'm not sure if Motorola can (or will) handle one-sie, two-sies and get it right.

****
The recommended "standard" configuration:

Item Price / each (includes Colorado State sales tax)

VP Oncore engine $268
Active Antenna $ 70
Cable to antenna $ 22

Total "standard" $360

****

Options to be considered:

LNA $ 16
battery $ 11

Shipping within the continental U.S., via 2nd day service, will run $10. This includes a box, packing foam and shipping charges. This figure is good for up to ten units.

Those interested in this group purchase should remit monies to the name and address below. Please send non-cash such as personal checks, money orders or the like, as it allows records to be kept much more easily. If less than 100 orders are placed, the checks/money orders will be destroyed, rather than incurring the cost of returning up to 100 of them. Alternately, if you want your check returned in the event of an insufficient number of units ordered, add a dollar bill to cover the cost of an envelope, stamp and my or my wife's writer's cramp which will inevitably result. If the order threshold is reached and an order is placed with Motorola, the $1 will be returned to you with your order. Please include a very complete address to which the order may be sent. Include your current Internet address and telephone number(s) where you may be reached, as well. I've experienced several Inet addresses which have bounced, by the way, so if you didn't receive a response from me directly, it was attempted.

Send orders to:

Thomas A. Bonomo
8147D Summerset Drive
Colorado Springs, Co. 80920.6123

I can be reached, and have been by several individuals, at:

Telephone: (719)593.9883 Home (evenings, weekends)
(719)592.5105 Office (weekdays)
Internet: tom.bonomo@cxo.mts.dec.com

This message will be posted to the newsgroups, as well.

Thanks for your patience as I've gathered information and responded to each of your requests.

Regards,

Tommy

Specifications and pricing information follows.

/\

/\

Motorola VP ONCORE SPECIFICATION DATA SHEET

Receiver Architecture
----
o 6 channel

o L1 1575.42 MHz
o C/A code (1.023 Mhz chip rate)
o Code plus carrier tracking (carrier aided tracking)

Tracking Capability
---
o 6 satellite vehicles simultaneously

Dynamics
---
o Velocity: 1000 m/s when altitude less than 18 km
o Altitude: 18 km for velocities greater than 514 m/s
o Accelleration: 4 g

Antenna
---
o accepts active and passive antennas

Acquisition Time

(TTFF = Time To First Fix)
o 22 sec. typical TTFF (with current almanac, position, time and ephemeris)
o 48 sec. typical TTFF (with current almanac, position and time)
o 2.5 seconds typical re-acquire

Accuracy
---
o Position: less than 25 meters, SEP (without SA).
DoD may invoke Selective Availability (SA), potentially degrading accuracy to 100 meters (2 dRMS)

DATUMs
---
o 49 std. datums, 2 user defined, default WGS-84

Signal Level
---
o TTL

Output Messages
---
o Latitude, longitude, height, velocity, heading, satellite tracking status (Motorola Binary Protocol)
o NMEA-0183 Version 2.00 (GGA, RMC, GLL, GSA)
o LORAN emulation mode
o Software selectable

Operating voltage
---
o 4.75 - 5.25 VDC, 50 mVp-p ripple

Operating current
----
o 230 mA typical @5V, 275 mA max at 5.25V

Standby voltage
----
o 2.5 - 5.0 VDC

Standby current
----
o 60 ua max

Dimensions
----
o 2.00" x 3.25" x .64" (50.80mm x 82.55mm x 16.26mm)

Weight
------
o 1.9 oz. (53.9g)

Connectors
----
o Digital: 10 pin (2 x 5) header on .100" centers
o RF: right angle OSX (sub-miniature snap-on)

Operating Temperature
----
o -30 - +85 degrees C (without on-board battery)
o -20 - +60 degrees C (with on-board battery)

Storage Temperature
----
o -30 - +85 degrees C (without on-board battery)
o -20 - +60 degrees C (with on-board battery)

Humidity
----
o 95% RH, non-condensing

Vibration
----
o 7.7 g, random (survivability)

MTBF
----
o >61,000 hours (estimated)

Optional features
----
o Lithium battery
o Low Noise Amplifier
o Real Time Clock

Pricing (includes Colorado state sales tax)

VP Oncore engine $268
Active Antenna $ 70
Cable to antenna $ 22
Low Noise Amp $ 16
Lithium Battery $ 11

Development Software
1st option $270
includes:
Raw code phase,
disc data,
smooth sat time,
carrier phase

2nd option $215
includes:
above without
carrier phase

One thing to note about the European telephone systems, what works in one
country may not work in another. While there are international standards,
they are not always implemented in every country.

"Typical" European values for telephone set operating parameters are:

Common Battery Voltage -48V dc
Operating Current 20 to 80 mA
Subscriber Loop Resistance 0 to 1300 Ohms
Loop loss 8 dB
Ringing Signal 16 to 50 Hz, 40 to 130 V rms

These are basically the same as in the U.S. Again, these represent
"typical" values and may vary among different European countries.

Another thing to think about is dialing. Dual Tone Multi-Frequency (Touch
Tone) dialing is not very common, even in some of the more advanced
countries. The pulse dialing in many countries is probably similar to the
U.S., but don't assume this is true everywhere.

Bottom line: Most U.S. phones using pulse dialing will work in most
European countries.

P.S. Notice that I didn't define Most ;-)

From: elendir@enst.fr
Message-ID: <2s0bnm$ee3@cismsun.univ-lyon1.fr>
Source record: 117698
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc

Hello !

I'm (still) planning to build a multimode multibander (VHF/UHF) rig.
In the course of designing the SSB part, I am of course facing the
problem of filtering the unwanted LSB.
I've talked on the air with several hams that seem pretty positive that
it is no more possible to find SSB Xtal filters in France.
Does someone have any clue regarding a possible US source for these ?
What I'd like to find out is a 10.7003 to 10.703 Xtal Filter, with at least
60 dB at 10.6997 MHz. But a 9 MHz look-alike filter (or any IF) would
fit also.

Thanks !
Vince, Fox 1 Romeo Charly Sierra

1264. Converting an old HT-220 to 2M

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-25 20:33:49 UTC
From: usenet@oracle.us.oracle.com
Message-ID: <1994May25.203349.11883@oracle.us.oracle.com>
Source record: 117699

I have a Motorola Ht-220 Type CC3540 Serial # L06K2D Model H33FFN1100E.
It transmits and Receives on 163.5375 MHz. It has a 15 Volt NiCad. It is
crystal controlled. I would like to convert this to 2 meter. Does anyone
know how I can do this? I should be able to swap out crystals, shouldn't I?
The numbers on the crystals (as best as I can tell) are:

xmit: 18170.8
rcv: 48912.50

What do these numbers mean and how are they related to the transmit
and recieve freqs? There is also a "PL Reed" that I will probably need. What
is this? Motorola wants $90 I DON'T THINK SO!. I'd like to substitute with
something a little less pricey.
Last (and least?) I need a charger for the Ni-CAD. I'd like to build
it myself. Any plans out there?

I live in Columbus Ohio but I travel extensively. I will soon be in
the Detroit Michigan area, anyone up there that can help me? Please respond
via email as my access to news is erratic.

My email address is:
dmarsh@oracle.us.com

So many questions, so few answers.

Doug N8TUT

Just wanted to mension that I have a set of 1994 , just published IC Master
which is compilation of all IC's and their sources and am willing to part
with it for $150 including postage. If you order it today it would cost
you around $200.If interested just drop me a line , I can swap it for
a good SW portable radio as well.

anis

In my opinion (and I'm chairing an administrative committee concerned with
such things), it *is* illegal: it's unauthorized computer access.
It is perfectly clear that this newsgroup is for discussing amateur
radio, not for advertising thigh cream. Thus, Mr. Keogh was using
numerous computers without permission (i.e., in a manner not permitted).

If it had happened at my site, I'd prosecute him under applicable laws.

Further discussion on administrative newsgroups such as news.admin.policy.

I have seen an increase of this noise recently, and would like to see
a stop to it also. So far, sending a friendly reminder that internet
is a non-commercial environment seems to help. The problem as I see
it is that so many new users are unfamiliar with the net, that they
treat it like a bulletin board. A few times, for the really bad repeat
offenders, I have reverted to sending them information on my friends
AMWAY products...several times a day...or sending a few core files that
I have been unable to figure out...;-) Even with all the nonsense posted
from these folks, the signal to noise ratio is still good enough to read
this group. Maybe we should ALL mail our core files and advertisements
to them....and their sysadmins...and don't you think they could benifit
from a few extra termcaps...Oh well, probably not. Just kidding ;-)

On a topic more related to the group, I have been making circuit boards
now for quite awhile using the direct iron on method from a laser printer.
So far it has worked for digital as well as RF and Video circuitry.
If anyone is interested, I am preparing information on how to do this.
I know that this topic has been discussed before, but I have a few twists
to add that have helped me quite a bit. (surface mount at home anyone?)

Oh well, have to go regenerate my pay now........

Hi there... I am wanting to build a DDS & DSP HF radio for my Electrical Engineering Degree thesis also doing some experimenting with HF Frequency Hopping Spread Spectrum - Which is not prohibited here in Australia.

To do this I was wanting to use the Qualcomm Q2220 Chip in association with the Techno-Wizzy One DDS VFO module from Elktronics-NE as mentioned in 73 Amateur Radio Today in December 1992. My father in in the USA at the moment so I arranged for him to purchase he parts although he reports something about the number being changed. Does anyone have an up to date address for this company or for any other companies selling a similarly priced kit?

Responces should usually be sent to drsmith@acacia.itd.uts.edu.au or 100026.3446@compuserve.com.

Many Thanks

Ramsey electronics has some cheap FM xmitter kits, they have a stereo transmitter too, based on the BA1404 chip, this chip is s a stereo generator, modulator and RF amp in a single package, puts out about 2mw by itself, but the ramsey kit hasas a transisto
r RF amp that kicks it up to 20 mw or so , I have one, works great.

these are the crystal freqs in KHz. the xmit crystal is 1/9th the xmit freq.

The recieve crystal freq = (recieve freq - 16.8MHz)/3 The 1st if is 16.8MHz. 2nd is 455KHz.

You'll have to tweak the front end recieve LC circuits some, but don't touch the IFs. And tweak all the xmit LCs. How to tell apart? You should get the service manual. Mine refers to H23ff...., so yours may differ some. You might need to add some tiny caps (both physically and in the pF range) to get the LCs down from 163 to 146.

There is also a "PL Reed" that I will probably need. What
>is this? Motorola wants $90 I DON'T THINK SO!. I'd like to substitute with
>something a little less pricey.
If the reed is "4A", it may be compatable with the local repeaters. or the reed circuits could be removed, but there's some small change to make to the squelch.

As for the NiCads, I wouldn't be suprised that they might be dead now. I mean not chargable anymore.

I've been using an HT220 board or my packet radio, crystaled on 145.07MHz. Coupled with a small power amp stage to generate about 8Watts. It's been going for 5 or more years in this service, and the friend who gave it to me had it this way (different freq's for voice work) ten or more years before. It just keeps on going.... We run it off a power supply, and I'm using a J pole antenna.

: I've talked on the air with several hams that seem pretty positive that
: it is no more possible to find SSB Xtal filters in France.
: Does someone have any clue regarding a possible US source for these ?
: What I'd like to find out is a 10.7003 to 10.703 Xtal Filter, with at least
: 60 dB at 10.6997 MHz. But a 9 MHz look-alike filter (or any IF) would
: fit also.

10.7 MHz SSB filters are rather unusual. However, I'm surprised that
amateur dealers don't sell useable filters. In the USA, you can often
buy optional filters to put in your amateur transceiver to get a different
bandwidth than what the radio came with.

However, the trend is to *make* your own filter out of microprocessor
clock crystals. For roughly $10 worth of crystals, you can make a
decent filter and have some crystals for the oscillator(s). They
even sell 9 MHz crystals.

I know of one world-class crystal filter manufacturer based in
France, C.E.P.E. part of Thomson-CSF. I've got one in front of me
now, but no address.

The highest reptation filters in amateur circles are German
KVG Kristall Verarbeitung Neckarbischofsheim GMBH
Postfach 61 D-6924 Neckarbischofsheim
Telefon 07263/648-0

John Birkett
25 The Strait
Lincoln
LN2 1 JF
England

Tel +44 522 520767

Often has surplus crystal filters in stock. I've bought a number of
marine quality 1.4 MHz IF usb, lsb, cw filters from him

The best advice is to first find your filters, then use IF to suit.

Recently a lot of 1.4 MHz IF filters of superb performance have
flooded onto the British market at very low surplus prices (I paid the
equivalent of 40 francs each, although the prices fluctuate) Filters
for AM RTTY and various CW bandwidths are also to be found as well as
proper separate USB and LSB ones. I think of good government surplus
components as a sort of tax refund!

Bon Chance!

1276. How can I reduce RFI from flourescent lights?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-26 15:50:20 UTC
From: philkeys@olympus.net
Message-ID: <philkeys-260594075020@ptpm004.olympus.net>
Source record: 117709

I have a beach cabin with solar panels & batteries for
power. I use 12VDC flourescent lights in each room
(made by REC Industries) with electronic ballasts.
When the lights are turned on I get all kinds of squeals
in the AM & SW bands. The 12 V negative line common to
the solar panels & battery is grounded with a 10 foot
ground rod (but driven into dry sand).

Any ideas how to quiet these lights? Now I have to
turn them off to use the radio.

Also does anybody have experience with the small 12VDC
to 120 VAC inverters (100W-200W)? Do they generate RFI also?

Thanks & 73
(these ham newsgroups are great, full of the latest info.)

>It transmits and Receives on 163.5375 MHz. It has a 15 Volt NiCad. It is
> xmit: 18170.8

The transmitter in these uses freq. triplers to get up from the xtal freq. to TX freq. 18170.8 x 3 x 3 = 163537.2. Mine is a 462 MHz unit that has one more tripler to get up there.

> rcv: 48912.50

Let's see... receive xtal = (Tx freq - IF freq) / n; where n = 3,9,27 etc. Using n=3 we get an IF of 16.8 MHz, which sounds reasonable. International Crystal Mfg. has crystals for these radios - call them at 405 236 3741 and tell them what you have. You may need model number and "chassis number" which is a number like NUE6001BA that you can find inside the battery compartment. The xtals are a bit pricey - $15 to $25 each, but what the heck, I only paid $10 for the radio at a flea. You will need to re-tune the tuned circuits in the radio, and for this you will need the Motorola manual... try Motorola or a local service shop for that. I copied the 450-488 MHz radio manual that another ham here had around. Make sure whoever knows you are re-tuning to a ham band, or else they'll want to know your commercial license #!

By the way, I have a line on cheaper crystals from a different source, still waiting for someone to get back to me on that.

>There is also a "PL Reed" that I will probably need.

This is pre-microprocessor coded squelch technology. A tiny mechanical reed functions similar to a quartz crystal, except at audio freqs. If you're going to use the HT to get into a repeater with PL tone access you need it, otherwise you don't, like for simplex. Mine came with one, but you could always add one of those tiny PL decode/encode boards from the back of QST.

> Last (and least?) I need a charger for the Ni-CAD.

Yah, these radios typically are placed in a "drop-in charger" which does the job. I'm not sure how I'm going to handle this myself... The battery that came in mine was good, though, and charged up to 15V no problem. Pick up a spare at a flea, as Moto wants something like $75 for them.

> Doug N8TUT

Good luck with the mods! I'll be doing mine as soon as I find out about those cheap xtals! Makes an interesting project...

I guess you could build some equipment to measure airflow or back pressure, but
actually I think that's usually done by the blower manufacturer and reported as
a design spec. In practice, what I've always done when building high power
amplifiers is to use blowers similar to those I see in others' similar
equipment. Not scientific, but it's usually worked.

And, yes, I've been in a few shacks in the old days where the final amp was in
a separate room to keep the noise down. Some of those folks invested a good bit
of effort in remote tuning gear, too.

1280. Help needed for external 22AT power

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-05-26 21:52:42 UTC
From: mmurray@leroy.cc.uregina.ca
Message-ID: <1994May26.215242.15420@sue.cc.uregina.ca>
Source record: 117582

My Kenwood 22AT has only one external power input jack located on
the side of the radio. Kenwood supplies a 12.5V 70ma adapter to
use with the unit. The adapter charges the battery but does not
have enough current to transmit with. I am planning on building
a simple 12V 3A power supply to used with the radio. My concern is
that I will be over charging the internal 6Volt 600ma battery.
Should I be removing the battery when using an external high current
power supply? Kenwood does not show a external AC power supply as
an option for this radio, but they do have a car adapter- which
could cause overcharging of the battery. Kenwood recommends a max
of 15 hours using the 12.5V 70ma charger.

Any suggestions?

Thanks in Advance.

What you might do is go out scavenging the ferrite loopsticks from old AM
radios. Then wind a couple dozen turns of zip cord on them and tape them
up. Connect the incoming line to one side, and the fluorescent light
fixture to the other. It should reduce the RFI somewhat.

But it depends on how close the receiver is to the fixtures. If the
fixtures themselves are radiating, then the only thing to do is replace
them with an incandescent lamp, or something similar. Maybe Kerosene?

Maybe a few capacitors across the incoming wires in each fixture might
help.

: I would appreciate a lead on where to find it.
: 73 de N1QVE
: Harry

You didn't give much info on what inductor, or where it was in the
circuit. You guessed about right. 2 turn links from one tank to another
sound about right.

Remember that some of the projects have been purposely made with
components that are hard to come up with except by buying them from the
project author. Some authors sell just a circuit board, and also the
hard-to-get parts. After all, they want to make money, even without too
many scruples. THey figure the buyer will be back for the hard to
get/make parts.

Remember, the first rule of project building is to get _all_ the parts
first. Right there... In your hand. Then you can start assembling.

: know how to bias these little demons so that they remain stable?
: I need to bias them at 0.15 volt, so that after applying a
: 0.05 volt modulating voltage they remain near their peak tunnel
: current, without strange things happening.

: Any help appreciated.
: Dave.

I'm checking the GE Transistor Manual, Rev 7th Ed, Chap 14. They show a 10 to 22 ohm resistor to ground from the TD cathode lead. This resistor must be less than the TD negative resistance. Also from the same lead, a 250 ohm pot (wiper arm connected to one end) in series with a ten ohm resistor which goes to a 1.5 volt cell.

Most schematics are using the 1N3712. They show several converters which seem simple in design. With cavities these TDs can go up to several GHz or more.

Source record: 117572

sebelt01@starbase.spd.louisville.edu wrote:

: I want to modify a pair of (cheap) walkie talkies to have greater range. I
: have three things in mind:

: 1 - Improve the antenna: 49.860 / 468 = 9.4 ft. Will a 9.4 ft length of wire
: do the trick? What gauge is _best_?

The FCC walkie-talkie rules used to say that the antenna was limited to 1
meter to be legal.

: 2 - Get rid of some resistors. It seems that there is a resistor right
: between a very small coil and the antenna. I'm not sure of it's purpose (does
: it just reduce the output power, or limit interference, or protect something
: in the transceiver? The resistor is labeled L2, with the coil before it
: labeled L1. (Which makes me thing it has somethign to do with tuning or
: interference).. If I remove this will my signal become stronger? (where I'm
: using these interference will be virtually no problem).

The L stands for inductor. It's probably for matching the short antenna
to the output stage. Also, it's probably a low pass filter, to reduce
harmonics.

: 3 - Add an amplifier. How hard is it to amplify the signal? Is it just a
: matter of adding on a resistor, or is such a circuit more comples. Again,
I'm
: not too worried about causing interference where these transceivers will be
: used, but I need to make them as powerful as possible.

The usual walkie-talkie is a single stage with the crystal and antenna
all connected. Cheap. But you could build another stage and put it
between the antenna and existing stage. You would have to find somewhere
to put it inside the radio, though.

Some people have reduced the resistors in the existing transmit stage to
get a little more power. But in doing this, it sometimes adds power to
the harmonics, and not to the frequency you want, the fundamental.
Another thing that's a problem is the reduced battery life. The battery
is just too small in these walkie-talkies.

: Thanks for any help/suggestions/whatever. Please respond by mail if at all
: possible, I will post a summary in the form of a how-to, if I can get this to
: work.

: John Ackermann AG9V
: jra@lawdept.daytonOH.ncr.com

Another way to get it into your PC is through the game port (what? you don't have one??). The 15 pin port on the multi I/O cards.

THe joystick has a resistor that's something like 150K total, and is about half that when the joystick is in the middle. All you have to do is get a CdS photocell and put it in place of the joystick resistor.

THere is a command in BASIC to read the joystick, and at the speed you're looking for, it doesn't seem to be a problem. One sample per second or so seems really easy to keep up with.

The 0-1mA from the chart recorder could go into a single transistor which then drives an LED which is glued to the photocell. Of course, you should use black silicon glue to keep out ambient light. The chart recorder might drive the LED bright enough without any amplifier.

Best of success.

Hi John, for such a simple application as this, I would use a printer port,
an external D/A and comparator. Drive an 8-bit D/A (Plessey ZN426) from
the printer port, use an LM339 to compare the D/A output to your voltage
(your current through a precision resistor) and read the LM339 output with
an input bit on your printer port. You now have a successive approximation
A/D converter. For one sample per second, you probably can't beat it. A
BASIC program can easily perform the software function.

Or you could use an Intel 80C196KB to do the A/D conversion and send it to
an RS232 port on your PC. (I'm in the 'C196 group)

I recently sat the UK Radio Amateurs Exam and have bought a Heathkit HW-7 to get on the air with. Unfortunately it came without manuals.

Also I have heard that there is a publication called
the "Hot Water" book with details of modifications ect.

Can anyone out there help me with these, or any other details of the HW-7?

9 MHz crystal filters "for the experimenter" are available from:

International Radio and Computer, Inc.
3804 South U.S. #1
Fort Pierce, FL 34982

Phone (407) 489-0956, Fax (407) 464-6386.

They cost $75 each. Five models for SSB range from 1800 Hz to 2400
Hz, with shape factors of 1.6 or 1.8. They also have models for CW,
AM, and FM. This company also makes filters designed for Icom,
Kenwood, Yaesu, Heath, Drake, and Collins radios.

I have no affiliation with them, I just happen to have their latest
catalog handy since I was looking into accessory filters for my rig.

Hear, hear! "I am not Heathkit" is my motto when I write projects for
Popular Electronics or the like; I use easy-to-get parts even if it cramps
my style.

What I particularly dislike are microcontroller projects with no listings
or exact specification of the software published. Practically universal
practice seems to be to treat the programmed microcontroller as a "black
box" available (of course) only from the author. This makes the project
article nearly useless to people who aren't actually building it.

I don't think I've *ever* built a published project exactly as specified.
I read them to get ideas. To me, withholding the software is as bad as
withholding the schematic would be.

I was always bummed out on electronic projects listed in magazines whenever they called for some esoteric part that you couldn't get locally.
The move these days is to publish a standard-type microcontroller circuit, and then charge folks out the kazoo for the software listing. Either that, or get it for free by contacting the author or magazine. Well, that's just great -- but what happens if the author dies, or if the editorial offices burn down? _Radio-Electronics_ magazine had a very useful BBS that they posted all the software for projects onto, but they refused to keep it running and is now defunct. Go figure.

I think we have some 8 pole crystal filters in the 10.7 Mhz range. They
probably are 7.5Khz wide. We have the exact specs. We would probably sell
them to hams for $10.00 each.

If interested please send me your fax number and I will fax the information.

I know 4khz filters at 10.7 Mhz were used in some Uniden SSB CB rigs.
They were quite good. You could put two in series. I think spare parts prices
were in the $25.00 dollar range.

It is hard to find asymmetric USB (and LSB) filters these days.
In a few years old design for 9 MHz IF, KVG XFM-9B01 and XFM-9B02
were used. I am not sure which one is LSB and which one is USB as
contradictory information was given in the article.

If you settle for a single symmetrical SSB filter, then different
BFO-frequencies for USB and LSB are needed, but the number of suitable
filters is much larger. One source for 10.7 MHz filters in England is
Cirkit (tel. +44-992-441306).

If you think about a single conversion design, 9 or 10.7 MHz IF is quite
low, usable at 144-146 MHz, but if you are going to use it on 70 cm,
you should put separate helical front end filters for the 432 MHz DX-
band and the 435-438 MHz satellite band.

[MosFet-Linear1
About a month ago, I posted my experience building a high-power solid-state linear using eight $1.50 MosFets, and very simple circuitry. I'm happy to report that it is working fine and exceeds my expectations, especially on 160 meters, where I can measure 600v P-P across the 50-ohm antenna output connector. This is 900 watts PEP....with the power supply delivering about 5 amps @ 160v. The actual peak currents would be 1.41 x greater for peak amperes of 7amps, for peak dc input of 1120 watts, for an instantaneous efficiency of 80% at the peak.
However, as usual there are always things to be changed or added:
I added a more-or-lesss conventional SWR bridge detector just prior to the 50-ohm antenna coaxial output connector....i.e. passed the ungrounded side of the output link which was passed through the hollow 1/4" copper tubing used as the resonant output coil. When the SWR reaches 2 or 3, the bridge-circuit generates currents exceeding 1 ma which is then passed thru the base-emitter junction of an NPN transistor, which conducts and shorts out the forward-bias line (common to all eight MosFets)...reducing RF output to a safe level. A 0-1ma meter in this SWR bridge output provides the usual viewing of SWR. I did not bother to include the Forward power option, altho that would be easy enough if desired.
Also, I was not too happy with the previous method of limiting In-Rush currents to the 10,000 uf filters, during power-up. As I mentioned, I like to turn my linear off-and-on frequently. As a matter-of-fact, my relay (which had been made more sensitive to facilitate time-delay) proved to be marginal.. and the contacts would stick closed ocassionally...and if not noticed, gives big trouble because of MASSIVE in-rush current....i.e. the zero-charge 10,000 uf capacitors look like a dead-short at the first instant! As a minimum, this will ruin a conventional heavy-duty toggle switch..usually welding the contacts closed, which becomes a safety problem, because you may assume you have switched it off, when in fact it remains ON! And although silicon rectifiers are amazingly tough, it will eventually get one of them. So.....
I have now changed the power-up circuit to a SOFT-power-up that I like very much. It may sound a little complicated to describe, but in reality is very simple to install: At a recent Hamfest I got a few used IRF-150 power M0sFets (100v, 40A, 0.055ohm) for almost nothing...although Newark sells them for about $3.50. To describe the circuit:
1. Begin with two 10w 50ohm resistors in series to limit the In-rush to the 10,000uf.
2. Allow 4 or 5 seconds to let this (100ohms) precharge the filters up to perhaps 80 to 100 volts.
3. Connect a MosFet across each of the individual 50-ohm resistors...Drain most positive-end, Source the other end....but leave both MosFets non-conducting for the first 4 or 5 seconds.
4. After about 4 seconds, one of the Mosfets will begin to conduct, and

and soon become a 0.055 ohm short.
5. After about 6 seconds, the second MosFet begins to conduct and soon becomes a 0.055 ohm short, thus shorting out the second 10-ohm resistor. So power-supply has come from 0 to full voltage in about 7 seconds, and has enjoyed a VERY SOFT turn-on. The main power DPST toggle switch only switches less than 2 amps max....i.e 1.41x120/100 into an instantaneous dead short.
6. To get the MosFets to do these nice things, we need two floating 9 or10 volt supplies, and to make it idiot-proof you should also use a DPDT relay. I could have used two junk-box miniature 12.6 ct transformers to create these two floating supplies, but I chose to use two DuraCell 9v batteries which apparently have a shelf-life of 5 years (At least the package said, install before 1999). The Mosfets have no conduction at zero gate-source voltage, but become a 0.055 ohm short with 9 or 10 v positive on the gate. I put a 1K resistor at the gate, which then goes to the "common" of as SPDT contact-set; The NC contact goes to the source, which assures that the gate is discharged to zero. Also the NEG of the 9v battery connects to the Source. The POS of the battery goes through a 5 megohm resistor on this particular MosFet (it will be 10 megohm on the other), to the NO contact of the SPDT contact-set. My relay is a 120v AC which gets energized immediately at power-up. The second MosFet is wired the same, except that its Time-Constant is twice as long, before it charges up to 9v and turns on the MosFet. Notice that the battery has no load current except a few microamps for a few seconds during power up. THE REASON that it is important to use a relay, is to insure that the 9v charge on the MosFet gates gets discharged immediately...otherwise it holds some charge for quite a long time (as I found out the hard way), so that if you power back up shortly after turn-off, they may still be in a highly conductive state, and additionally, one must assure that the 100v rating is not even momentarily exceeded. Note that at turn-on, there is an instantaneous 170v (120 x 1.41) imposed across the two 50 ohm resistors.. i.e. into an initial dead-short. This would exceed the 100v rating, except that the two equal resistors ensures that this is shared equally at 85v each (this is why it is important that both MosFets be non-conding at turn on and until the pre-charging has reached 70 or 80 volts so that the remaing voltage difference will not exceed 100v when either MosFet begins to conduct.
7. Note that the MosFets only dissipate a small amount of power for a short period before they "short themselves out"....so no heat-sinks are required. As a matter of fact, I mounted them by literally soldering the Source-pin directly on the NC contact terminal on the relay which is quite sturdy. (I do a lot of "air-wiring" on my experiments). Also, the 9v DuraCell terminals take solder nicely, so no need for special connectors. Remember however, that the batteries are floating at the 170v level, so the cases should have adequate insulation, and also should not touch each other.

The Ham Radio hobby, for me, is more experimenting than it is operating, and consequently I have already purchased sixteen IRF-710 MosFets @

$1.49 (IR)..from Newark (Mot are $1.12)...these should be a little faster and may work better on 80 meters, and possibly 40 meters with minimal complication. One Data manual suggests that the most important rule-of-thumb for faster switching, is the Gm/Rev-Cap (Gfs/Crss) ratio. The IRF-710 is considerably better than the IRF-722's that I am using now. I plan to use eight in parallel for each half of the push-pull...total of 16. I will increase the source resistor from 2-ohm, to 3.3-ohm.

Note that the present design (at least on 160 meters) is approaching the ideal limit for the simple 1:1 resonant tank-circuit in the output, i.e. each drain is quiescently at 160 volts, and can only swing between 320 and zero (more practically, 310 and 10 for a p-p value of 300v. Because of the push-pull resonant tank-coil, and the auto-transformer effect, this results in 600v p-p across the total coil and thus across the 50-ohm ouput link to the antenna and this is what I measure with an oscilloscope...i.e 900w.

Thus, getting higher voltage across the coil, will require the drains being tapped down a little from the coil-ends..perhaps 10 or 20% from each end... representing perhaps a drain-to drain impedance of 30 to 40 ohms, and so paralleling more MosFets will meet this requirement.

Practically speaking however, note that the present 900w available is only down about 2.8 db from the legal maximum of 1500w, so it would hardly be worthwhile...except that 16 MosFets would be virtually loafing. A bigger advantage would be realized on 80 meters, and probably 40 meters.

Ferraro14 (ferraro14@aol.com) wrote:
: Is anybody expirimenting with the techno whizzy dds or any other DDS.
: Has any body read the two tech articles in QST by Rohde on receivers

No, yes, both.

But seriously... Have you seen the data on the various Qualcomm devices, and those from Analog Devices ? The AD7008 seems to be THE device now. I've got one running on its demo board.

Ulrich Rohde's articles are very important, but I wonder whether they will be fully appreciated. He is exactly right about the very poor distribution of gain in the usual Japanese transceivers, and the effect it has on receiver performance. As the bands become more crowded and the adjacent broadcasters buy still more watts, this will become even more important. The existing radios seem to have their gain profile planned to minimise the need for internal screening above all other considerations.

He suggests a low frequency DDS with a PLL frequency multiplier following it. This has some good points, and some bad ones. A DDS alone, like the Technowhizzy, can work nicely as a transmitter but runs into problems in a receiver. DDS quantising noise terms will be 60-70dB down on the output signal, and will be present at various frequencies over (and a little beyond due to limitations on practical filters) the full tuning range of the DDS. The exact frequencies of these quantising components will move around as you tune the DDS. Putting a PLL between the DDS and the receiver structure, either in a multiplicatice role as Rohde suggests, or in an additive structure as done in current production radios will impose a tracking filter effect on the LO, which will remove quantisation components that are outside the loop bandwidth (usually kHz to at most tens of kilohertz)
The worst case is if we tune the DDS to a frequency where its output is close to a quantisation component - close enough to pass the PLL. The true input to the PLL is the vector sum of the DDS wanted output AND the quantisation component. The difference in their frequencies and the amplitude limiting effect of the PSD in the PLL will let this be treated as a phase-modulation sideband. The PLL will pass this phase modulation. In an additive system, the component is passed to the receiver LO signal at its same strength relative to the wanted signal. In a multiplicative system, the PLL multiplier will multiply the phase modulation, giving an unwanted output 20 log (N) dB higher than before (N is the freq multiplication factor for the PLL)
This does not rule out such systems, but it does point out that DDS quantisation is more critical, and some art is needed in the choice of

frequency ranges to try to avoid the very worst cases, if possible.

Rohde is right, the system he suggests is simple and elegant. For an upconverting radio, the LO needs to cover less than an octave, so a fixed ratio PLL is OK, which allows better loop design as the effects of variable N need not be allowed for. With the current progress of creating better and better high speed DACs, I think it may be the way to go. If a new DAC offers better resolution and glitch energy, the quantisation components will be reduced. If a new DAC offers faster speed for the same quantisation component levels, then the PLL can be designed with lower N, and so reducing the multiplication factor, thus making a cleaner LO.

The thing to beware of is that these systems look fine at some frequencies, and only produce problems at a few regions.

Cheers
David GM4ZNX

Hello everybody !

Thanks for your helping answers. I finally got a filter (in France) - 10.7 MHz with 2.2 kHz bandwith. It went with the lateral Xtals (10.6985 MHz in my case). But I have taken note of the different addresses you gave me.

The choice of the 10.7 MHz IF is not innocent. I am aware that one of the problem when using packet radio is PLL locking time between RX and TX. It takes about 200 ms, if your step is really small. By using a 10.7 MHz IF for both TX and RX, I completly eliminate this problem, since the PLL remains on the same frequency. I can also use a very cheap ceramic filter to filter the FM.
I know little about helicoidal filters, so I d be pretty interested in knowing more. Also, I d like to know what frequency swing you can expect from a Xtal oscillator modulated by a varicap diode.

Many thanks again ! And 73 from F1RCS, Vince, QTH : Paris.

Oh BTW,

: Have you considered a phasing sideband generator?

Yes. BF shifter is a bit complex. Unless using a FIR to implement the Hilbert filter.

Connaisez-vous "Handbook of filter synthesis" par Anatol I Zverev,
John Wiley and sons inc New York 1967 ISBN 0 471 98680 1 ?
chapitre 9 "Helical filters" . c'est le tome definitif pour le dessein
mathematique des filtres.

Also, I d like to know what frequency swing you can expect from a Xtal
: oscillator modulated by a varicap diode.

(sorry, my French isn't adequate for this part..)

It depends a lot on the frequency, the circuit, and production
tolerences. With care a 200 ppm (parts per million) tuning range can be
reasonably reliably achieved for a favourable frequency and circuit.

beware that overtone crystals are far far harder to pull. In general
terms, if you have two crystals at the same frequency, the overtone one
will give a swing reduced by a factor roughly equal to the square of its
overtone number.

Example:

A 25 MHz fundamental crystal in an oscillator circuit with a swing
of 100 ppm. replace the crystal with one with its third overtone at 25
MHz, and you'll get about 100/(3^2) = 11 ppm swing ! (very roughly!)

If the tuning range is important, use a funamental crystal at a
suitable frequency, and use frequency multipliers.

Beware of attempts to pull an oscillator too far, you'll suffer from
temperature dependant failure to start, etc etc.

Bon chance

I got the Qualcomm Q2334 dual dds from Cain Technology, (602) 966-4322
FAX (602) 968-5132. It comes in 3 speeds - 20 ksps $69 in onesies -
30 ksps for $79 and 50 ksps for $209.

I am using two TRW TDC1012 12 bit 20 msps DACs for the two outputs.
(Can we spell quadrature spread spectrum? :>) I can not remember what I
paid for them but they were not real cheap. Invest in a PC proto board, if
that is the route you want to build around, that has the interface
electronics built into the board. It sure simplifies life. They run about
$70 for a 16 bit board.

My crystal is an Anderson Electronics model 601 20 MHz. Their number is
(814) 695-4428.

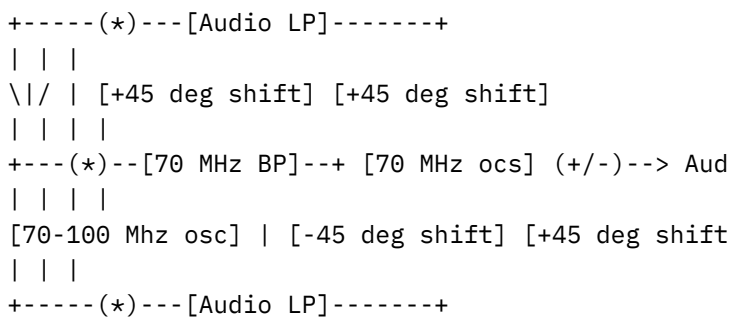
Hope you find the parts you need! The Qualcomm literature has most of the
info you need for building a spread spectrum setup.

Pat

1314. simple SSB receiving methods

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-06-01 11:25:53 UTC
From: agterkam@fwi.uva.nl
Message-ID: <2shr81$br8@mail.fwi.uva.nl>
Source record: 117602

Currently I'm planning to build a receiver, who doesn't.
However, my intension is NOT to use Xtal filters and NOT
to use a large number of OPAMPS to create sharp lowpass
filters. My plan is to use a phasing method instead.
The basic setup is as follows:



The 70 MHz BandPass and Audio Lowpass filters will be of a
(passive) LC type (width bandwidth). My problem then is:

The audio phase shifters of +- 45 degree do have to be precise
and do have to have a bandwidth of 20 kHz or more.
At the moment this seems to be difficult without OPAMPS or a large
number of resistors and capacitors.

Can anyone give me some advice on how to solve the phase shift
problem. Does a simple and inexpensive method exist to phase
shift a wide spectrum of, lets say, 100 kHz by 45 degrees ?

Thanks in advance, Dirk. e-mail: agterkam@fwi.uva.nl

1315. Getting a VFO on-frequency (W1FB Design NB p. 111)

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-06-01 12:09:34 UTC
From: sct@po.cwru.edu
Message-ID: <2shtpu$h0m@usenet.INS.CWRU.Edu>
Source record: 117603

I'm working on the DC receiver on page 111 of _W1FB's Design Notebook_
as a first homebrew project. It sure has been educational... :-)
The current problem is that the VFO insists on operating around 5.5 MHz.
I need it up around 7 MHz if this is going to be a 40m receiver. It's
a JFET Hartley VFO with a 4.8 uH inductor tapped 1/4 of the way up for
feedback, 100-125 pF of tank capacitance, and a 100 pF capacitor coupling
the top of the tank circuit to the JFET gate. I'm using an MPF102 for
the JFET. The circuit is built dead bug style.

The values shown for the oscillator work out to 6.5 MHz to 7.25 MHz if I
ignore the 100 pF gate capacitor. How much is that capacitor going to
pull the frequency?

Does the design look sound, in general? I double-checked my wiring
and component values several times. Any other suggestions for things I
should check?

>Jeff
>AB6MB

I sell a couple of kits based upon the Qualcomm chip, including
a PC-based one, so I am a bit biased.

I don't know what the low-quantity price is, but it should be
around $30 or so.

One thing about the 73 kit article: the DAC used is really used outside
its spec range. Most of the parts will work fine, but use a spectrum
analyzer to check your spurs.

I can make available postscript files of my kit schematics for anyone
interested, send me email. The DAC I used is the Motorola MC10322P--
pretty good for the price. My current favorite is the Analog Devices
AD9721, but it's pretty expensive for hobby use. The best
inexpensive one (10-bits) seems to be the Analog Devices AD7128
at the moment.

Source record: 117605

I purchased a Novatech DD3 kit for about $100. This kit is based around a 32 MHz. Qualcomm chip, and is meant as a sort of demo board. I modified the input by placing latches there to create a PC parallel port interface. I use this board in my homebrew 80m transceiver with an IF of 4.9152 MHz. In this application, several spurs are noticable, for the reasons given by one of the previous posters. They are not really objectionable, as they are at the LSB resolution (2 Hz) and can be easily tuned around. My present software is keyboard controlled - I use the up/down keys to give me a large frequency change, and the left/right keys to give me a small change. My preference is 1000 and 100 Hz, respectively, but this is also programmable.

A second set of latches contains the transmit frequency, which is switched on when I depress my key. The software automatically updates this transmit register whenever I change frequency in the receiver so that the correct offset is maintained. As was correctly stated previously, the deficiencies of the DDS as a receiver LO are not noted in my transmitter, due to filtering and the fact that I am using a class C amplifier on the output. My lab's spectrum analyzer shows that all harmonics are at least 45 dB down from the carrier, even with the DDS being used as a "direct drive".

Some noise reduction on the Novatech board will allow better performance. For example, the clock driver design allows a fair amount of 32 MHz to come out the back door (verified with a spectrum analyzer). I modified this circuit and replaced the rather cheap PCB trace with coax to help reduce this. Also, to save money they use an 8-bit DAC, even though the Qualcomm output is 10-bits. I'm in the process of replacing this one as the quantization noise is very high with only 8 bits.

Overall, quite interesting to play with, and certainly more stable than any analog LO that I have built. It also makes a good direct drive CW transmitter source. Future work here will involve a nice, user friendly GUI for the PC...

You could use the Weaver ("Third method" of SSB generation).
I believe it is covered in the ARRL Handbook. Briefly, you
replace the audio phase shift networks with a pair of mixers,
fed with 90-degree-out-of-phase oscillators with a frequency
in the middle of the audio passband. When you sum the mixer
outputs, you get USB or LSB, depending on whether it's a
+ or - 90 degree phase relationship. Oh, by the way, the
low-pass audio filters at the mixer inputs have a cut-off
frequency of 1/2 the audio bandwidth (just below the
oscillator freq).

Thanks for the responses on my request for ideas on measuring air flow around a transmitting tube, or otherwise protecting it from too much heat.

1. Several mentioned the manometer, a "U" shaped piece of tubing or glass that contained water. When inserted in the chamber of air flow, the change in water height indicated the pressure.

2. One mentioned that the people at Eimac used to put ribbons on the exhaust of the air system socket and make sure the ribbons blew straight up.....

3. The idea I like the best is the use of temperature sensitive paint on the base of the tube. It was recommended that a few temperature ranges be painted on the base. The tube specs have the max. allowable base seal temp. All I need to do now is find a source.

From: myers@cypress.West.Sun.COM
Message-ID: <2sivec$lni@abyss.West.Sun.COM>
Source record: 117609

Does anyone have empirical information on the phase noise floor of the dividers in the Motorola CMOS PLL chips, such as the MC145157 and MC145170? I'm tending to guess towards -150dBc, a number I've seen published for CMOS dividers, but is this accurate?

This is of particular interest with respect to the on-chip reference divider in the Motorola CMOS PLLs. I would guess the phase noise level of the reference frequency, when driven with the on-chip oscillator using a crystal, is going to be primarily determined by the divider.

Any comments?

To subscribe to the QRP mailing list do the following;

email to majordomo@think.com

Subject: You can leave it blank

subscribe qrp or unsubscribe qrp to quit receiving it.

It is automated so you will receive an reply telling you that they got it.
Then shortly there after and sometimes along with it you will receive
the QRP mailing list. There are new messages constantly being sent as it
is very active.

Have you tried spreading or squeezing the wires together on the inductor?
I think he mentions somewhere in his book that you might have to do that.
Hope this helps!

It has been my experience that you'll need to play with either squeezing the inductor windings closer together (or moving them farther apart), or try some different caps to get resonance at the correct freq. You also might try a small trimmer at the gate (rather than the 100 pF) to find a value that doesn't pull the freq, but allows reliable start up. Stray capacitance and inductance is probably the culprit here. This is what experimenting is all about. Don't get frustrated (I did, it doesn't help)--just play with it until it works!

Good Luck

: Subscriber Loop Resistance 0 to 1300 Ohms

600 ohms MANDATORY is France.

: Loop loss 8 dB
: Ringing Signal 16 to 50 Hz, 40 to 130 V rms

: Another thing to think about is dialing. Dual Tone Multi-Frequency (Touch
: Tone) dialing is not very common, even in some of the more advanced
: countries. The pulse dialing in many countries is probably similar to the
: U.S., but don't assume this is true everywhere.

Thanks ;-) We have been using DTMF since 10 years now. All the country has
DTMF capability !!! We are not the third-world of telephony :-)

From: sct@po.cwru.edu
Message-ID: <2sklj5$leb@usenet.INS.CWRU.Edu>
Source record: 117615

Thanks for the suggestions. I already fiddled with the winding spacing
and that improved it by about 400-500 KHz. (It's hard to tell exactly,
since I'm using an oscilloscope to measure frequency by comparing the
VFO output to a 7 MHz crystal oscillator.)

The idea of replacing the tank capacitor with a trimmer is a good one.
I'll try pulling a couple windings off the inductor first, I guess.
It looks like I should lose 5, give or take 1.

Hi Mike:
When using an external power supply you must disconnect the batteries
. Whether you actually remove the batteries or install a switch to select
battery or power supply operation is up to you.
The only over-charging side effect I'm sure of is drastically
shortend battery life. I believe that they could also leak or explode.
Good Luck.

I have been following the stream on the Techno Whizzy DDS thinking
Somewhere along the way someone would define DDS and some of the other
nemonics used but no one did :(. I am quite familiar with PC interfacing
and DAQ's (digital acquisition) but have no knowledge of spread spectrum or
the terminology used for spread spectrum. If someone would post a brief
explanation it would make me very happy :).
Thanks in advance.

> All I need to do now is find a source.

When I used to work with induction heating equipment I found that the steel industry often uses temperature sensitive "crayons" which melt at various specific temperatures. These were for forging and annealing temperatures however, and I'm sure you don't want your transmitting tube bases glowing bright yellow. They may make lower temperature crayons as well. I'll see if I have some at home and determine the manufacturer if you wish.

heiss@ualr.edu (heiss@ualr.edu) wrote:
: I have been following the stream on the Techno Whizzy DDS thinking
: Somewhere along the way someone would define DDS and some of the other
: nemonics used but no one did :(.

Not sure about the "Techno Whizzy" part, but "DDS" stands for
"Direct Digital Synthesis."

A normal phase-locked loop (PLL) synthesizer uses a voltage-controlled
oscillator (VCO) which is phase-locked to a high-stability crystal
oscillator reference. To allow changing frequency, there is a
programmable frequency divider between the VCO and the phase detector,
so that the output frequency can be any integer times the reference
frequency. For example, if the reference is 10 kHz, the VCO frequency
can lock to N times 10 kHz.

A DDS synthesizer, on the other hand, generates the sine wave output
signal directly using a digital-to-analog converter (DAC). The DAC
output changes state at a rate much higher than the highest
sine wave frequency desired. To get different frequencies, the DAC
simply shortens or widens the width of the cycles it is outputting.

The advantages of DDS are very fast frequency switching and finer
frequency resolution. The disadvantages are limited upper frequency
range, complexity, and often poorer spurious performance.

So there's a few mnemonics to get you started, DDS, PLL, VCO, DAC...

Hi netters...

I'm looking for a good (ie. working) schematic for a VCO ranging from approx 430 MHz up till 500 MHz (70 cm amateur band). Maybe someone can post or mail me an example how to do this. The exact specs are not that important, just the idea how to build the thing.

Thanks a lot.

Squeezing or stretching the turns only gives a small (but sometimes useful)
variation on frequency. With the values indicated; the oscillator should be
working above 6.5MHz- so something is wrong. Is the coil indeed 4.8uH?
Perhaps it is something more like 8.2uH? The 100pF gate coupling capacitor
seems a little large. At 7MHz a value like 3.9 or 4.7pF is more usual
(lighter loading of the tank). And (this may start an argument) leave out
that useless little diode at the gate- it does no good that I can see, and
sometimes causes a deterioration in output and stability.

A handy formula for tank circuit work (particularly VFO tanks) is:

L = 25330 divided by (FMHz SQD X CpF)

and

C = 25330 divided by (FMHz SQD X LuH).

and by transposing for F:

F = SQ RT of [25330 divided by (LuH X CpF)].

Message-ID: <Ju0s2b7.bratton205@delphi.com>
Source record: 117522

Ok I have put together a system like you want. One way to do this cheap is to use Motorola Micors. Get a Micor pull out the VHF receiver build a 9.6 reg. an an audio interface board add a CW ID and feed this to a Motorola Mocom 10 UHF Tx and buy yourself a dual band Vert. and you have a remote.
At the repeater put up a UHF beam and take a Micor for UHF and build a 9.6 reg. and feed this to the Hall unit and you will have a great system.
I am still working on the audio it is too sharp but in time we will work it out. good luck.

1339. Looking for GE UHF MVP radios (407-420MHz or 450-470MHz)

Newsgroup: rec.radio.amateur.homebrew

From: phil@hansen.ncd.com
Message-ID: <2slvq5$r8n$1@rosebud.ncd.com>
Source record: 117525

I am looking to put a full-duplex link up between two of my 1.2 GHz repeaters.

Does anyone have a source for GE UHF MVP radios?

The link would be in the 420-430 link band.

I understand that there are two versions of the MVP that might work. One is
for the 407-420 MHz band and the other is 450-470 MHz band. Although the
450/470 version may take more tuning to get it down to 420-430 area.

Anyone have a line on these radios?

Thanks!

Phil
de KJ6NN

P.S. I like the MVP since it is small enough to fit into the tight rack space
that I have at the repeater site

>
> -Tom, KA8HML
> tew+@cs.cmu.edu
>

Not likely. This HT, a nicely done piece of work at $40, uses a cordless
phone PLL chip which doesn't appear to lend itself well to 6m operation.

The less expensive xtal controlled HT, however, is easily modified for
6m, so I'm told.

I bought the service manuals for both of them (I own both), and plan to
experiment with them. The T/R switch on them is nothing. The transmitter,
with a specified output power of around 10mW, simply drives the common base
front end along with the antenna. There is a choke in series with the
short antenna, all designed to provide a legal Part 15 field strength.
Doesn't look too hard to boost to higher power levels for amateur use,
but a real T/R switch is required and the spectral purity is suspect.

Maybe I'll just use them as an IF for a transverter project...

1341. Periodic Announcement - ARRL Email Information Server (info@arrl.org)

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-06-03 03:00:06 UTC
From: mtracy@arrl.org
Message-ID: <rec.radio.info-arrl.email.info_770612404@ve6mgs.ampr.ab.ca>
Source record: 117531
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.digital.misc,rec.radio.amateur.homebrew,rec.radio.info

Periodic Announcement - ARRL Email Information Server (info@arrl.org)

The services that the ARRL provides via the internet include the
Email Information Server and the Technical Information Service.
The Information Server is an automated mail server that gives you
access to many of information files relating to various facets of
Amateur Radio. You can retrieve any or all of these files by
sending an email message to info@arrl.org here at ARRL HQ.
Each file you request is then mailed to you automatically.

To use it, mail messages to:

info@arrl.org

Each line of the message body should contain a command as shown below.
The subject of your message is not processed and may be omitted. You
may place as many commands in a message as you want. The files you
request will be sent to you in separate messages. Only ASCII text
files are supported.

Valid INFO commands:

reply <address> (may be needed - see below for explanation)
help
index
send FILENAME (example: send prospect.txt)
quit

In the above message example, "help" retrieves a brief set of
instructions for info, "index" retrieves a list of available files
and "send prospect.txt" retrieves a text file containing information
on becoming a radio amateur.

Note to users with FTP capability: All of these files are also
available by anonymous ftp to oak.oakland.edu in the
pub/hamradio/arrl/infoserver area. Retrieve the file index.txt
in the /league sub-directory for a complete listing of available
files.

If you want to retrieve several text files with one message, use a
separate line for each "send filename" request.

Your From: field or Reply-to: field in your header should contain a
valid Internet address, including full domain name. If your From:
field does not contain a valid Internet address, the answer will not
reach you. If this is the case, then use the reply command as shown

above. When needed, this command should always be the first command in your message.

IMPORTANT: Please use the quit command in your message. This will prevent processing errors from message signatures.

PLEASE NOTE!: This is an automated system not capable of handling written requests. Any questions on the info-server or the content of any of its files should be directed to mtracy@arrl.org.

ALSO NOTE!: Do *NOT* reply to messages sent from info@arrl.org - the reply address is redirected to keep bounced messages from endlessly looping. Write a new message to info@arrl.org instead.

The Technical Information Service gives League members on the internet better access to the knowledgeable technical staff here at ARRL HQ. Questions relating to Amateur Radio and related technical topics are welcome. To use this service, send a normal e-mail message to tis@arrl.org with your question spelled out in plain english. For best service, be as specific as possible and keep your line length in messages to a maximum of 80 characters. Due to personnel limitations, priority will be given to questions from League members.

Best Regards,

Michael Tracy, KC1SX, ARRL Technical Information Services Coordinator
(e-mail mtracy@arrl.org)

Sample of files available from INFO: (There are lots more!)

Note - If you are not yet an Amateur Radio operator retrieve the file prospect (send prospect) for information on how to easily get started in this fun hobby.

Agreed. I have modified the little xtal controlled beast and it works nicely.
Even got a couple of states with it when 6M was really open. I think the HT
might be modifyable, though, but it's going to take more work.

If you want more power, look into boatanchors. There are a lot of military
field radios that will cover 6M and which can be had for a song. Fair Radio
has a nice assortment, and I picked up a PRC-10 for $20 at a hamfest
myself.

>
> David GM4ZNX

Actually, with the right circuit, you can reliably pull a fundamental
crystal 1000 PPM (i.e. +/-500 PPM). If necessary you can increase that
to 2000, 3000 or even 4000 PPM with some degradation of phase noise
and temperature stability. Similarly, 3rd overtone crystals can be
reliably pulled 100 PPM and 5th overtone crystals can be reliably pulled
40 PPM.

How do you do this? Build an LC Colpitts oscillator at the frequency
of your crystal (get it within a few %). Now, insert the following
circuit in series with the
emitter of the transistor: the crystal in series with the tuning diode
in series with an inductor which resonates with the diode at the xtal
frequency when in the middle of the diode's tuning range. Finally,
install a shunt inductor directly across the crystal such that it
resonates out the C-zero of the crystal at the crystal frequency.
C-zero is typically 5 pF. Make sure this inductor has a high enough
SRF (i.e. >> xtal frequency). Note that the finished oscillator has
3 inductors.

If you have starting problems, you might have a VHF parasitic oscillation.
The old trick with a ferrite bead on the base or collector will fix this.
A 2N5179 is a good transistor to use.

>And (this may start an argument) leave out that useless little diode at the
>gate- it does no good that I can see, and sometimes causes a deterioration
>in output and stability.

Sorry, Drew, you're right -- I've gotta argue with your statement. The diode has a very noticeable and measurable beneficial effect on stablility. Both Wes, W7ZOI, and I have confirmed this. The diode acts as a clamp, never conducting more than very, very slightly. It prevents the FET gate-source diode from conducting, which would load the tank circuit, reducing its Q and increasing drift. In my experiments, a schottky or germanium diode does degrade the stability, for reasons I've never investigated. Perhaps it's because of the larger reverse leakage currents of these types. But a 1N914-type silicon diode does effect a very apparent improvement in stabililty.

June '94 QST has an article (part 2) on receiver design which if I read
the thread correctly, concludes that it would be good to leave this diode
out...that it contributes to phase noise. Just wondering if this is
relevant to your discussion.

1348. Schematic for WEFAX?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-06-03 19:21:39 UTC
From: paweiss@ellis.uchicago.edu
Message-ID: <1994Jun3.192139.15561@midway.uchicago.edu>
Source record: 117535

Hi, new here; am I in the right place?

I'm looking for a schematic for a WEFAX decoder, like the ones they sell for ~$75, going from the headphone jack of a shortwave recv. to the serial port of an IBM compatable. I got a bad copy of one in spain, and the communication problems kept much information from being passed (for the longest time, I thought they were giving me the secret diagram, turned out to be a circuit diagram :)), and would like to try again.

Thanks,
--

1351. Best freq for 6M AM simplex?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-06-03 22:28:02 UTC
From: John Nordlie <UD167958@NDSUVM1.BITNET>
Message-ID: <94154.172802UD167958@NDSUVM1.BITNET>
Source record: 117538

I'm working on a project with annother ham to convert some radio shack toy walky-talkies (49 MHz) to 6M. Having never worked 6M before (and I don't know anyone in the area that has), I'm having trouble finding out what freq I should use. The HT's are crystal controlled, so I'd like to get the freq right on the first try. What should I use for AM simplex? I'd like to stay far away from the calling freqs, DX, and FM. Anyone have any suggestions?

Thanks in advnace.

The 6 meter AM calling freq. is 50.4 Mhz. Try it, you might meet
somebody there. Chances of winning a lottery are somewhat better.

>June '94 QST has an article (part 2) on receiver design which if I read
>the thread correctly, concludes that it would be good to leave this diode
>[from the gate of an oscillator FET to ground] out...that it contributes to
>phase noise.

My reading of the discussion in the article is:

- The added diode can increase phase noise, but "merely including a gate-clamping diode does not guarantee higher phase noise".

- Added noise occurs only under some conditions of feedback.

A footnote (number 12) credited to the editor (presumably Dave Newkirk), states that

- The diode does improve frequency stability. Equal stability can be achieved by applying the correct amount of source bias, instead. However, determining the proper amount of source bias isn't as simple as adding the diode.

Rhode uses a schottky diode elsewhere in his circuit. It may have been "obvious" that a schottky diode would be better than silicon as a gate clamping diode, so this may have been what Rhode used in his experiments. I don't know how the two might differ in their noise-adding properties.

I don't believe that phase noise is an important consideration in a VFO unless the oscillator is used as a reference in a phase-locked loop with high multiplying factor, or the oscillator is multiplied to a much higher frequency. Perhaps a professional receiver designer could comment on this.

1358. What's the DAC for?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-06-04 18:35:16 UTC
From: dlleigh@frank.harvard.edu
Message-ID: <1994Jun4.143517.32939@husc14.harvard.edu>
Source record: 117545

I've been reading Ulrich Rohde's article in the June issue of QST. In figure 14 he shows a block diagram for a DDS-driven PLL. The DDS feeds a DAC, which gets filtered and then hard limited. This hard limited signal (a square wave) is then used as an input to the PLL.

My question is: what's the DAC for? Why not just drive the PLL with the MSB of the DDS. It's seems like a waste to make a nice filtered analog signal from the DDS output and then just make a square wave again.

My guess is that is has something to do with decreasing phase noise, but I don't see how it does that. Does anyone have any ideas?

FIRST CALL FOR VOTES (of 2)
unmoderated group sci.electronics.cad
unmoderated group sci.electronics.repair

Newsgroups lines:
sci.electronics.cad Schematic drafting, printed circuit layout, simulation.
sci.electronics.repair Fixing electronic equipment.

Votes must be received by 29:59:59 UTC, 21 June 1994.

This vote is being conducted by a neutral third party. For voting questions only, contact the votetaker, Brennan T. Price <gt0670e@prism.gatech.edu>. For questions about the proposed groups, contact Mark Zenier <mzenier@netcom.com>.

CHARTERS

SCI.ELECTRONICS.CAD

sci.electronics.cad is an unmoderated group for the discussion of Computer Aided Design software (and systems) for use in designing electronic circuits and assemblies. Topics can include Schematic "Capture" software, Printed Circuit Board layout software, introductory and educational use of circuit simulation software such as Spice, obtaining simulation descriptions (Spice models) for electronic components, and any other computer software that relates to designing electronic circuits at the printed circuit board level.

SCI.ELECTRONICS.REPAIR

sci.electronics.repair is an unmoderated group for the discussion of repairing electronic equipment. Topics to include: Requests for assistance, Where to obtain servicing information and parts, Techniques for diagnosis and repair, and Annecdotes about success, failures and problems with equipment manufacturers.

HOW TO VOTE

Erase everything above the top "-=-=-=-" line and erase everything below the bottom "-=-=-=-" line. Do not erase anything between these lines and do not change the group names.

Give your name on the line that asks for it. For each group, place a YES or NO in the brackets next to it to vote for or against it. If you don't want to vote on a particular group, just leave the space blank. Don't worry about spacing of the columns or any quote characters (">") that your reply

inserts.

Then mail the ballot to: gt0670e@prism.gatech.edu
Just Replying to this message should work.

-=-=-=-=-=- Don't Delete Anything Between These Lines =-=-=-=-=-=-=-=-
sci.electronics.* Ballot <SE-0001> (Don't remove this marker)

Give your real name here:
If you do not give a real name your vote may be rejected.

[Your Vote] Group

[ ] sci.electronics.cad
[ ] sci.electronics.repair
-=-=-=-=-=- Don't Delete Anything Between These Lines =-=-=-=-=-=-=-=-

Anything else may be rejected by the automatic vote counting program. The votetaker will respond to your received ballots with a personal acknowledgement by mail - if you do not receive one within several days, try again. It's your responsibility to make sure your vote is registered correctly.

Only one vote per person, no more than one vote per account. Addresses and votes of all voters will be published in the final voting results list.

Hello everyone,

I am a in need of the documents/schematics for the following:

Heathkit Power Amp.
model HA-202

If you have them and would be either willing to negotate for them
or make a copy of them, please e-mail me. The Heahtkit power amp
ha-202 is a 2 or 3 transistor c-class that had the option for a nice
black case with fins on top. Very nice design, and unfortunately, something
has gone wrong with it. I am representing Synton Amateur Radio Club
of the University of Illinois for this, so it would benefit a ton of
people if you decide to contact me. (we misplaced the documents
unfortunately)

sorry about that last line there.

73's et hope to speak with you soon,

Allen Hall n9rzc@uiuc.edu
Pres. of Synton ARC UIUC (W9YH)

Thank-you Roy. I read that part (in Solid State Design I think). However, I stand by what I have said, having built literally hundreds of different VFO's (both bread-board and "finished"), my observation is that the diode does little to improve frequency stability.

I would dearly like to know who started this diode hoax- for that's what it is- and just about every USA-published circuit perpetuates the myth.

Dirk, maybe this is one of those areas where no really simple approach will give satisfactory results. See Richard Hosking's paper in Electronics & Wireless World, Mar. '94, where he describes a direct conversion receiver using the polyphase method. Details are given for an experimental polyphase audio phase shift network and also a cunning way of obtaining your 90 degree L.O. signals. Perhaps not as simple as you would wish however.

73, Drew, VK3XU Telecom Australia Research Laboratories.

>Cirkit (tel. +44-992-441306).

10.7Mhz is not exactly well suited for high quality SSB crystal filter design. Crystals DO change frequency with both temperature and time. Not all crystals, even of similar cuts, change the same way by the same amount. Hence the crystal filter characteristics will change with temperature, such as for Field Day operation, and with time, due to crystal aging. Most of my designs selected much lower IFs when I had the luxury of "doing it right." 5MHz was the highest I figured was marginally acceptable.

>If you think about a single conversion design, 9 or 10.7 MHz IF is quite
>low, usable at 144-146 MHz, but if you are going to use it on 70 cm,
>you should put separate helical front end filters for the 432 MHz DX-
>band and the 435-438 MHz satellite band.

Wellllll, single conversion is not nice no matter how you do it unless you are REALLY anxious to maintain low power operation. For VHF I'd go to a dual conversion with first conversion up to the 70Mhz to 140MHz range. For UHF I'd consider a first IF of 70MHz quite workable. For 144MHz - who uses it? (LA bias. {^_-}) For 144MHz I'd use a 21.4MHz 16KHz wide filter in the first IF and double convert to between 455KHz (mechanical filters) to 5MHz. (I find the filters required in things like Syntors to be a royal PITA because of their necessary narrow bandwidths. They are required to reduce the half-IF response as much as anything. (Fr +/- 1/2 Fif response) I'd rather select something a little less stringent based on requirements for reducing chances of front end overload and if possible custom tailor it to that function.

(I designed VERY high dynamic range radios for DoD usages for about 20 years before I discovered software burned my fingers a LOT less than soldering irons and was easier as well. At least one design was able to operate with no alteration in BER when receiving -109dBm signals in the presence of inband -5dBm signals (which was as high as I could conventiently generate with the test lashup.) So I have a half an idea what I am doing and am TERRRRRIBLY opinionated. I also do not reveal ham licence call for reasons of privacy having faced a nasty threat based on it.)

Um, 200ppm pretty much wants more than a simple varicap to make it happy. Even with carefully selected (and spurious de-Q-ed inductors) past 200ppm it is remarkably easy to get into odd spurious oscillations due to crystal spurs. As you mention, I'd never try pulling an overtone crystal farther than its base frequency tolerance at best. (I learned that one the hard way. Just barely made that one work.)

There is no single number you can attribute to a noise floor. I satisfied myself of that one with MECL and TTL many nasty years ago. You CAN, however, make some interesting calculations that prove to be fairly accurate. The first stage is perhaps the most important one. It is the stage which converts your oscillator signal into digital. From there most of the rest of the noise can be "neglected" for first approximations. The problem comes in when you divide the input frequency. The more you divide the more the input noise, which is basically DC to infrared or so, aliases onto your desired signal. By the time you have divided by a thousand or more this becomes "significant" in low noise designs.

As an aside, I find it amusing to be worried about noise when using the on chip oscillator. They do not usually drive a crystal into a highly stable low noise regime. Nor would the onchip conversion from the chip's oscillator to digital be all that low noise.

1368. SMALL HT POUCHES 4SALE

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-06-06 06:17:53 UTC
From: ddevera@bbs.dsnet.com
Message-ID: <wcJHNc6w165w@bbs.dsnet.com>
Source record: 117558

****

VERSA-POUCHES

****

!!!!!!2 VERSIONS!!!!!!

YAESU FT-11R and small HT owners,

For those of you that have requested HOLD DOWN STRAPS on the VERSA-POUCH,

We now have another version of the VERSA-POUCH with hold down straps. Which

holds down your HT and prevents it from falling out of the case.

Because of this new version, the CASE PRICE will slightly increase to 6.00 per

case, 5.50 for 2 or more. If interested please send a reply message ASAP.

The makers of this pouch will only produce, these POUCHES with hold down straps,

by request. So let me know how many you want and we'll take it from there...

Depending on the size of the order, it'll take 1 day, for single pouches to

1 Week plus, for larger orders. Also, because of this NEW VERSION, the VERSA-

POUCH can be customized to fit MOST small HT's, but you'd need to pay & order

in advance.

PRICE BREAK DOWN:

MODEL #: VP-1-NS

Regular Pouch, no hold down straps = $4.00 or $3.50ea. for 2 or more.

MODEL #: VP-1-WS

NEW VERSION Pouch, with hold down straps = $6.00 or 5.50ea. for 2
or
more.

Even for $6.00, you still can't go wrong!!!!

PLEASE DO NOT FORGET TO INCLUDE SHIPPING...

Thanks again to many of you for your interests and suggestions... SPREAD
THE

WORD...

73 David.

>
>Radio shack walky-talkies are FM not AM.
>
>--
>Rick

Rick, Good Buddy, I didn't write the text attributed to me in your post.
Please check your attributator.

I did advise the originator that 50.400 Mhz is the AM calling freq. and
that almost nobody is ever there, at least out here in Oregon. I do
occasionally monitor 50.4 as well as 52.525(FM calling freq) and do
hear signals on 52.525 when conditions are right or the locals are on.
I would like to use my Clegg 99'er sometime. Please get on 6 meter AM
and call CQ if you can. While operating 10 meter AM a JA station told
me that 6 meter AM is popular in Japan while 10 meters is mostly FM over
there. I have yet to work a JA on 6 meter AM, not to mention another
state besides Washington.
Why isn't 6 meters used for satellite operation?

Someone makes a series of stick on labels which have a range of dots that change color according to the max temperature that they were exposed to. The brand Tempril maybe or Tempilabel perhaps? Used to stick them on power transistors and heat sinks when I worked in the field.

Of course you need more than a simple varicap to get 200 ppm (see my previous post). I happened to need to build a 19.2 MHz. VCXO last week, and I had no trouble tuning 4000 ppm below series resonance and 2000 ppm above series resonance (that's a total of over 100 kHz.). When I tried to go above 2000 ppm on the high side, I did have some (predictable) trouble jumping to a spurious xtal response up there.

1375. Converting the Radio Shack 5ch 49MHz ht to 6m

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-06-06 21:04:00 UTC
From: sorgatz@avatar.tti.com
Message-ID: <1994Jun6.210400.21750@ttinews.tti.com>
Source record: 117562

Well, this isnt how I wanted to publish this, but it seems that
it's necessary. The 5 ch units are pll controlled and if you look
at the schematics you will notice that the base freq for the pll
is xtal controlled. If you look closer you willl also notice the
Aussies have a version of this thing running in the 55MHz area
and the only difference is the pll xtal!

Therefore, find a xtal at or near 10.24 MHz - this will give you
operation from 50.610 MHz in 15KHz steps. You might also want to
reduce the size of the final transistor's bias resistor, 8-10Kohms
seems to increase the power out greatly..like 450mW or so, but the
battery life is dramatically foreshortened! Peak and tweek as needed.

It's not good for repeaters, it's not powerful, but it IS CHEAP!
..and it is 6m FM which is really fun at hamfests, swap meets and
the like where everyone else is competing for the usual 146.52 and
223.5 and such like.

Next time I'll tell you how to easily convert a cheap CB ht to
run at 29.6MHz...with FM optional!

I am selling a homebrew 40 meter cw transciever. It covers 7.000-7.075
and about 7.100 - 7.175 mhz, puts out about 2 watts. The receiver is a
direct conversion type, but uses very good audio filtering.

The rig was based on the article in August 1980 issue of QST by W7EL and
improved with better double tuned band pass filter and a chebychev filter in
front of the audio preamp.

I am also selling a 65 Watt computer power supply (I believe it came out of an
XT).

Any inquiries, please email to bad1679@ultb.isc.rit.edu

Thanks..

>signal from the DDS output and then just make a square wave again.
>
>My guess is that is has something to do with decreasing phase noise, but
>I don't see how it does that. Does anyone have any ideas?

Yeah. The noise output of a DDS synthesizer is determined, in part, by the
DAC. In theory, the maximum attainable signal/noise ratio of the DDS is
6dB * Number of DAC bits. A 10 bit DAC promises 60dB S/N, a 1 bit DAC promises
6dB S/N.

There's a trick, though; the spurious noise output of a DDS is not always
evenly distributed; sometimes it isn't distributed very much. This has the
effect of producing an output which is mostly very clean with a limited number
of severe spurs.

In the case of using the MSB only, there would be some specific frequencies
where the output was a very clean, symetrical square wave. However, at most
frequencies, you'd have an asymetrical square wave which is different from
cycle to cycle; serious phase noise.

Even when you limit a sine wave into a sqaure wave, you don't change the
noise due to phase variations (i.e. phase noise) (limiting does reduce/eliminate
noise due to amplitude variations). Therefore, to get a low phase noise square
wave from a DDS, you need to generate the lowest possible noise sine wave, then
limit it.

Does this help?

Message-ID: <2t0af0$q88@lynx.dac.neu.edu>
Source record: 117565

Reading the recent messages about adapting radio shack HTs to 6M got me thinking

I have a pair of Radio Shack CB HTs with an A and B channel in which you can place crystals. I also have a (1 or 3 watt) larger HT with 3 channels

I am wondering: How hard would it be to get these HTs working on 10M ? Simply put new crystals in and be ready for QRP FM operation on 10M?

Please send a copy of any responses direct to me also (j.perry@lynx.dac.neu.edu)

Thanks!

Source record: 117567

Hi Everyone,

Earlier, I had mentioned in a posting that I had a few twists on this topic.

If you can get your hands on a copy of Midnight Engineering (Jan-Feb 94 I think) There is a pretty good article on doing just this.

There are some companies that are selling specialty media for this purpose.
My experience with them is that they work OK, but are spendy (OK, so it's only $2 per sheet, but I'm really cheap). What I have found that works the best is Ink jet paper.

To recap the basic process:

1) Print the circuit board image on a laser printer, reverse image using whatever computer and drawing package you have available.
(I prefer using ORCAD with a Postscript driver, but have used a Mac 512 with MacDraw in the past)

2) Register both layers (if you are doing two sided boards) on a light table (or against a window looking outside at the daylight)
Tape three sides of the papers to form a little envelope.

3) Slip a peice of copper circuit board into the envelope you made.
You will have to make sure that it is big enough to cover all the traces, but small enough to fit into the envelope.

4) Iron one side of the circuit board thoroughly, using the edge of the iron as much as possible. When in doubt of whether the toner is sticking to the board, iron some more (more is better) you should spend about a minute or two per side. Turn the board over, iron the other side.

5) Peel off the paper and etch using ferric chloride (I haven`t tried the other chemicals, but they should work fine)

6) Clean off the excess toner using steel wool, ajax, etc.

7) Drill and fill.

Special twists and notes:

Some folks like to drill before etching, that works OK, but I like to see the results first before I drill it. If you drill afterward, you might lift pads here and there. Practice helps. If you drill before, sometimes the edges of the hole will etch too.

Use Ink-Jet printer paper, the smoothest you can find. Because Ink-Jet Paper has an absorbant coating (usually clay coated to aid in drying time), the fibers of the paper usually do not get imbedded in the toner.

Earlier, I had experimented with a variety of papers, and found these to work the best. Other papers tend to leave paper fibers in the toner which is fused into the copper, this tends to make pin-holes in the etched board.

Before you try peeling the paper, let it soak in water to loosen the paper. Because the clay coating is put onto many of these types of paper with water, water tends to loosen the paper from the clay coating. I usually let them soak for a half-hour or so, but have soaked as little as 5 minutes, or as long as overnight with no adverse effects. The board soaked overnight required little rubbing to loosen the paper, the board that only soaked for 5 minutes took a lot of rubbing with the fingers to get all of the paper off. A lot of it depends on the paper being used (I am using Tektronix ColorQuick paper, but since I work for Tektronix, it is cheap and plentiful...your milage may vary).

Use the sharpest drill bits you can find. Check with a local dentist to see if they have any dull dental burrs you can have, or buy some from the local hobby store.

I have been using a Tee-shirt press to laminate my images to the circuit board. Having a compliant rubber surface works a lot better than using a hand iron.

A friend of mine is using a small iron from a hobby shop used for applying heat shrink plastics to remote control airplanes. I plan to make a press out of an old waffle iron (two heated surfaces) and some silicone foam pads. Again, the rubber of the Tee-shirt press tends to do a much better job of laminating the toner to the board than using a home type iron.

After making the circuit board and cleaning thoroughly, I have taken another laser print of the parts placement silkscreening, and laminated it to the board using the same process, it looks really impressive. I have also laminated the solder resist layer onto a finished board, this also looks good, and has the added bonus of protecting the board from oxidation while still allowing it to be soldered.

You may have to touch up the board with a permanent ink marker, but in the 25 or so boards I've done so far, this has only been necessary on the first few. Oh yeah, so far, this method has worked for RF, digital, surface mount down to about 8 mil traces (use a good printer for these), and of course, through hole.

I`m working on through hole plating next, but that is a little more tricky. Midnight Engineering had a good article on doing that in some issue?

Thanks to all those who sent me E-Mail, sorry I didn't have time to reply directly, but work keeps me pretty busy. I hope this helps.

The usual disclaimers apply, your milage may vary, etc.

>rkarlqu@scd.hp.com
I have calculated and simulated circuits which allowed that much tuning range.
Stability analysis of the results left me "unimpressed." If I wanted that much
tuning range I'd find another route to happiness unless DESPERATELY in need of
low power. (Um, a surprisingly good approach would be a SAW oscillator based
VCO and a mixer to the lower frequency. And it'd be about as stable as a 19MHz
oscillator pulled 100KHz. Analysis showed stability was more determined by the
capacitors and inductors used than the crystal once you'd be even a quarter of
the way "out there." Of course my definition of "acceptable stability" may be
much more stringent than yours. I was designing stuff for DoD type apps. {^_-})

(Of course the last RF design I did was near a dozen years ago and was a quite
different design than the sorta thing you were looking at here. How'd you like
a workable design (not schematic - just design) for a frequency synthesizer
that'd take 10MHz in and give an output between 9.999997 and 10.000003MHz
with one or two part in 10 to the 13th step size.)

Dana: I am not sure this is as simple as you make it out to be. The
polarity of the sinewave after the DAC is determined by the MSB before the
DAC and the squarewave after the limiter (1 bit quanterizer) is determined
solely by the polarity of the sinewave. If the DAC and the limiter were
perfect then the output of the one bit quantizer would be exactly the same
as the MSB before the DAC, i.e., the only differences are due to error in

the conversion process from digital to analog to digital. I believe that the phase noise out of the entire synth. loop will not change if you eliminate the DAC and use the MSB out of the DDS, which means that the DDS could be simpler also or that the phase noise is pretty bad in either case.

DUAL BAND HT 4SALE

****

Have 1 DJ-580T, ALINCO RADIO 4$ALE, w/ ACCESSORIES. This is a
nice

little HT, I have one of my own. The HT is barely 1 Month old and

like NEW.

If you buy NEW(with NO ACCESSORIES) it'll cost you just under
$420,

depending on where you live and what ur sales tax is.

Selling this radio for $335.00 + Shipping with a few accessories:

* MICROPHONE

* PLUG IN LIGHTER ADAPTER

* RADIO CASE

If intersted, let me know... ASAP...

73 - Dave!

This is incorrect. The MSB at the DAC input has a jitter of half the clock
period, because it can only change state at a clock transition. The
reconstruction process of D/A conversion and requantizing lowers the jitter
at the limiter output by (on the order of) 6 dB per bit of D/A resolution.
This is because there is a time interpolation effect that allows the limiter
to change state in units of 1/2^n fractions of a clock period.

This topic is a very common source of misconceptions about DDS.

The simplest way is to use a VHF or UHF radio as an IF and build yourself a transverter. Probably the cheapest way too.

1392. Ten-Tec Direct conversion kit -- getting on frequency

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-06-07 18:22:42 UTC
From: vinod@watson.ibm.com
Message-ID: <2t2dti$1a1l@watnews1.watson.ibm.com>
Source record: 117495

I recently got the Ten-Tec direct conversion receiver (kit #1056), and put it together for 80m. (The kit comes with parts for all the different bands). My intention was to use it for receiving W1AW code practice. After I put the kit together, I was able to receive various signals, but mostly seemed to be digital modes, and perhaps couple of beacons, but no W1WA.

After checking that I had used all the component values they specified for the frequency determining circuits, yesterday I went over to a friends house, to check it out with an oscilloscope. After playing around with all the adjustments they specified, we found that the lowest we could go was about 3.8MHz, and the highest was about 4.3MHz. No wonder I could not get W1AW, which is at 3.5815 or so..[The specs say that the 80m module should get me between 3.5 and 4.0MHz].

Now, I am new to this stuff..so, if you can tell me what I should try to get this fixed, I would appreciate it very much. The receiver uses an NEC612AN mixer-oscillator (similar to NE602 according to the documentation).

Here is what I plan to try:

1. Resolder all the frequency determining components.

2. Try changing (ie increasing the capacitance) of the circuit which determines the local osciallator frequency. (Currently C3=150p, C4=150pf, L2=8.0uH, L3=8.2uH, C3 connected between pins 6 and 7, C4 connected from pin 7 to gnd, and L2 and L3 connected in series from pin 6 to Gnd through a 0.1pf capacitaor, and a varactor tuning circuit connected to the top of L2 ie aafter the 0.1pf cap).

3. Any other suggestions?

Many thanks in advance for any help, advice you can offer.

This analysis leaves out the effect of the anti-aliasing filter between the
DAC and the limiter. Because of the "memory" of the filter, the filter output
will cross zero at some time dependent not only on when the DAC output crosses
zero, but also dependent on the DAC levels before and after the zero-crossing.
It is this extra information that allows an "interpolation" of zero-crossing
times to much finer resolution than the DDS clock period. Using just the MSB
produces edges that are rounded (in time of occurence) to the nearest clock
period; resulting in much higher phase noise.

>Aussies have a version of this thing running in the 55MHz area
>and the only difference is the pll xtal!

Slow down, Erik. Changing the 10.24 Mhz crystal also changes the
channel spacing. This could make it difficult to interoperate with
other synthesized radios on 5kHz channels, since you'll be on 5.774Khz
channels (for example).

The other little detail you're leaving out is that the 10.24 MHz rock
is used to provide the 2nd mixer injection. Changing this rock
changes the 2nd IF. Oops, now you have to change the 2nd IF filter.
Not necessarily practical.

You *are* referring to the 5 channel radio, catalog #21-402, right?
If so, there is no mention of the Aussie radio in my service manual.
The TRC-505 does have an Aussie version at 55.05Mhz, but it is
crystal controlled, i.e. no PLL.

> Therefore, find a xtal at or near 10.24 MHz - this will give you

Oops. Never mind that the T/R switch is non-existant, that, even if
you change the "PA" bias and actually get 450mW (where'd this number
come from? Experimental results?) that the front end isn't designed
to cope with 13V p-p (that's 450mW in 50ohms). Are you talking about
the TRC-503 radio?

If you analyze the spectrum on the MSB of the accumulator output you will find
that it is particularly rich in spurious.

DDSs have two terms which determine their theoretical spurious content. One is
the number of bits in the sine table's output and the other is the number of
bits in the sine table's input. When these two numbers fall to 1 you will
discover that the levels of spurious produced are "unpleasant" at best. A
case in point would show this phase noise. Suppose each cycle is divided up
into somewhat less than 5 accumulator clocks. Not a lot less, though. First
you'll notice that the MSB output is no longer a square wave. Second you will
note that it is in fact a 2 clocks one side and 3 the other side wave which
periodically swaps sides for the 2 and 3 clocks. ANalyze this sort of waveform
for spurious,

Now take the same thing and run it through a sine table. The zero crossings on
the sine table are much closer to a "regular" period and describe something
much closer to a squarewave - within one accumulator clock. If you follow the
DAC with a filter this jitter is itself reduced. (You have a trade off here,
though. For many apps you may be able to replace the DAC with an N bit
comparator with the other input set to "zero". Thanks for pressing the issue
so I'd have this insight. MSB is not enough, as I said. But a digital
N bit comparator may be as good as an N bit by N bit EPROM sine table.)

Hello Anko,

My favorite osc. from HF to UHF range is the Clapp (like a Colpitts but with varactor added in series with the inductor to ground) as shown, among other places, in U. Rhode's book "Digital PLL Frequency Synthesizers", Prentice Hall, 1983. To get "Stable" (!) operation, insert a base resistor and an Emitter resistor (about 22 ohm, both) before connecting C1. For 430-500 MHz, I would use NEC's NE68033 (or its siblings in other packages) or the Motorola MMBR571 (or other packages in the family). C1 (between Base and Emitter) 15pF, C2 about 12pF, L can be 3 turns of #26 AWG with 0.1 inch air core (please excuse me for the US units). For varactors I'll use a pair of MV2102 back to back.

Bias the varactors' common Anode with a 1 uH choke and 100p bypass. connect one Cathode directly to ground and then DC ground the other end through the tank's L and then a parallel combination of 1 uH and a 560 ohm resistor. The parallel resistor is needed to de-Q the spurious resonances. The transistor's Base now sits at DC ground, so we'll need a positive Collector supply (5-8V) and a negative Emitter supply (say -6V through a 330 ohm resistor). If you need more tuning range, then either use Frequency Sources KV3201 or four MV105 connected back to back with bias chokes. After all these messy descriptions, you probably still not getting the picture. So just email me if you can use a schematic in Postscript.

Good luck!

Benjamin

: signal from the DDS output and then just make a square wave again.

: My guess is that is has something to do with decreasing phase noise, but
: I don't see how it does that. Does anyone have any ideas?

Let me see if I can explain it. The concern here is quantization
noise. Consider a sampled sine wave signal, say a 1.1 MHz signal
sampled at a 4-MHz rate. The sample values would be:

x(k) = sin(2*pi*k*1.1/4)
so,
x(0) = 0
x(1) = 0.987688341
x(2) = -0.309016994
x(3) = -0.891006524
x(4) = 0.587785252
and so on.
Actually, there are more digits to the right of the ones shown: an
infinite number of digits, in fact. But any DAC can have only a finite
number of bits, so for each value shown above, the DAC can output only
an approximation of the desired value. So, the DAC is usually going to
be outputting a voltage slightly different from the correct one. This
difference, or error, is noise. (In the case of a DDS, the noise shows
up not as random "white" noise, but at discrete frequencies--spurs.)
The larger the difference between the correct sample value and the
value the DAC has to output, the more noise. And this is controlled by
the number of bits of the DAC.
So, if we remove the DAC and just use the MSB of the DDS, we'll have
huge errors for most of the output samples, which will show up as huge
spurs. For example, thge samples above would have to be:

x(0) = 1
x(1) = 1
x(2) = -1
x(3) = -1
x(4) = 1

(Counting any sample with the MSB = 0 as a 1 voltage and any sample with MSB = 1 as a -1.) Not a good thing; the error (noise) is as large as the signal! And you can't count on the bandpass filter to remove the spurs generated this way, since some of them may occur close in frequency to the output signal.
Hope that helps.

From Stanford Telecom's book on DDS

A frequently asked question is this: The output of the NCO is
a digitized sinewave and the most significant bit (MSB) is the
sign of the signal. So can't I just use this signal when I only
want to generate a squarewave...

The answer is yeas and no: it all depends on the jitter that can
be tolerated on the square waver. Where does this jitter come from?
To answer this it is necessary to recall that the output of the NCO
is a sampled data signal, not a continuous time signal, since the output
of the NCO can only change at the edges of the clock. The MSB is
a replica of what would be obtained at the output of the clipper if the
low pass filter were omitted. When the output frequency fo is an even
submultiple of the clock frequency ... (no problem)
...
However, consider the case where the fo/fclk = 1/7.5. This is shown in
Fig. 3 (sorry can't draw this in).
In this case the sinewave starts at zero degrees and the first rising
edge of the MSB coincides with this zero crossing of the sinewave. The
second zero crossing occurs after 3.75 clock cycles and the MSB changes
after 4 cycles; the third zero crossing occurs after 7.5 clock cycles and
the MSB changes after 8 cycles; the fourth zero crossing occurs after 11.25
clock cycles and the MSB changes after 12 cycles; the fifth zero crossing
occurs after 15 clock cycles and the MSB will change simultaneously. What
has happened is that the MSB of the NCO has
generated two cycles of a rectangular wave, the first with a period of 8 clock
cycles and the second with a period of 7 cycles. This process repeats, so that
the mean period
of the signal is correct, 7.5 clock cycles, but with a jitter of plus or minus
a half cycle since the periods are actually alternately 8 and 7 cycles.

...
when the ratio between fo and fclk is more complex is that the statistics
of the jitter change; the peak-to-peak value of the jitter will always be
one clock cycle, but the RMS value will vary and so will the spectrum of the
signal.

...
The reason why a jitter-free signal is obtained when the sinewave from the
DAC is clipped after filtering is that the aliases of the signal are
removed before the harmonics are generated, and consequently the aliases of the
harmonics are never generated in the first place.

From: sorgatz@avatar.tti.com
Message-ID: <1994Jun7.222219.11120@ttinews.tti.com>
Source record: 117489

Please note that the existing xtal in the RS 5ch 49MHz unit is 10.24 MHz! Substitute a 10.4 MHz xtal (its a common xtal used in many vdt and vtac circuits - $1 at most surplus type places.) in it's place and your little ht will have 5 channels starting from 50.610 MHz with 15 KHz spacing.

You will have to tune the cans and the final for peak output, but the adjustment is very slight. You might also be able to push the freq a little with a different freq xtal, we tried a 10.7 and found it to be beyond the tuning range of the cans. So try a 10.45 or 10.5, maybe even a 10.6 MHz would work.

The easist way to do this mod is to do a pair and tune them together, this is what KB6LUZ, Dennis and I did on our initial pair. Thereafter we used my FT726r and his Yaesu 6m rig to do the tuneups. A longer telescopic antenna helps the range, we picked a pair of 4 section antennas at RS. These stick out from the top of the ht about 3-4" but are the same base diameter as the ones supplied with the ht for 49 MHz use. I think they are 26" as opposed to 18" long. Whatever antenna you decide to use, tune the final to it using a field strength meter to guide you.

73! Sorry for the mixup on the xtal freq!

THE ARRL HANDBOOK HAS A CHAPTER THAT DISCUSSES HOW PHONE PATCHES OPERATE.
IT IS QUITE INTERESTING, AND INCLUDES SOME INFORMATION ON A BASIC, MANUALLY
OPERATED PHONE PATCH.

An autopatch is a more complicated beast and would take a lot of work to
build. You are probably better off buying a commercially made autopatch,
or simpler yet, join a local repeater club that has an autopatch on their
machine.

If you decide to set up your own autopatch, make sure you take care of
compliance with the FCC rules. The issues (particularly control issues)
get complicated fast when dealing with autopatches.

I thought so; I calculated 10.4 MHz to move from 49.85MHz to 50.61MHz.
The channel spacing 15.23 KHz, close enough for most radios.

However, this means your second mixer injection is now 10.4 MHz, not
10.24 Mhz. This change is probably narrow enough to remain inside
the passband of your first IF filter (a ceramic 10.7MHz jobby maybe
as much as 300KHz wide), but means your radio is going to be most
sensitive to signals 160Khz away from where you expect. In fact,
I'd expect the receiver to be rather deaf at the expected receive
frequency, since the 2nd IF filter is pretty narrow (< 30kHz).

In the absence of an on-frequency signal, there's probably enough
signal leaking through the 2nd IF filter to demodulate the signal,
but the sensitivity has to be poor. Do you retune the quad
detector coil (L107), too? I'll bet that makes the audio sound better,
but it won't make the radio any more sensitive.

The L7250 Sanyo synth chip uses ROM lookup tables to determine
frequency, so compensating for the oddball offset of 160KHz in
the IF response isn't easy. What did you do about this?

Yeah, but unless I'm mistaken, you're going to run into the 2nd
LO issue, too. Even worse.

I think the mose economical thing to do would be to make a transverter rather than a complete transceiver. You could use an HF or 2M all mode rig as the IF.

I seem to recall, back when we first got use of the band, several designs appearing in places like QEX and the now defunct Ham Radio Magazine.

The DDS works by keeping track of the number of Reference clock pulses required to generate a cycle of the output frequency. Quite often this is not an integer, and the Accumulator overflows at different intervals to give you an average frequency that matches what you want.

If only the MSB of the phase accumulator is used then the edge of your output signal is jumping back and forth to give you this average frequency. The DAC with the Sine table has an interpolation effect to give you less jitter (a deterministic form of phase noise), as additional information about the correct zero-crossing time is embedded in the other bits of the accumulator. As a result the edge jumping is reduced to some small percentage determined by the phase-quantization (how many points along a cycle do you have entries in the table) and DAC resolution (how many different levels between + and - peaks of the sine wave). Now you can sense the zero crossings and recreate a square wave with a much more stable edge.

I think this question has been answered plenty well enough by other
posters, but to extend the thought, have a look at "Reducing Spurious
Output of NCO's" on page 48 of June 1994 NASA Tech Briefs. The
article talks about a (NASA-patented) technique for adding dithering
to an NCO (DDS system) to reduce the level of the spurs.

Would it be practical to add a 10.4 MHz oscillator for the PLL but
retain the 10.24 MHz oscillator for the second mixer? Sorry, I don't
have the schematic, so I can't see whether this is reasonable.

How about leaving the 10.24 MHz crystal in place, but use a mixer (NE602?)
and filter to move the 49 MHz PLL output into the 50 MHz band? I suppose
that enough filtering to avoid ~46 MHz spurious emissions would be more
work and bulk than is worthwhile for the rig.

Barry

There are two that I know of, Vamp Inc has McCad EDS and Douglass
Electronics also has a system for the Mac. Both offer Schematic Capture,
PCB Layout and Autorouting among other features. I don't have any real
experience with either one, but I believe they will send you a demo disk.

Address:

Vamp Inc.
6753 Selma Ave.
Los Angeles, CA 90028
(213) 466-5533

and

Douglas Electronics Inc.
2777 Alvarado St.
San Leandro, CA 94577
(510) 483-8770

Hope this helps.

Regards

Ken

>---

I've used both of these packages >VERY< extensively ...

Douglas: Cheaper. Less featureful. I kinda prefer the layout tools in Douglas if I'm going to do totally-by-hand merely using the computer instead of tape & mylar. The schematic capture was good. The autorouter bites. Poor use of color. (I have to admit: I was using a somewhat ancient version)

McCad: I use this almost exclusively now. I don't like the schem capture as much as Douglas' (Douglas does bussing much better) but I just LOVE the layout stuff. It was MUCH more intuitive than Dogulas, and dealt with multi-layer more gracefully. It was much more expensive ($10K). I also had to build quite a few devices for the schem capture that I thought should have come with it (they did in Douglas). Good use of color.

If you're only going to do 2-layer boards, and don't mind the lame autorouter, go with Douglas.

If you're going to do serious layouts, (like for money) spend the bucks and get VAMPs.

Douglas had no copy protection.

VAMP used scarred-disk, but you could install 3 copies, or use the master copy as a key-disk, and it came with 2 copies of every disk.

1420. PCB layout software for PC

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-06-10 12:15:10 UTC
From: gdian22@rfc.comm.harris.com
Message-ID: <Cr6KpB.9G5@news.ess.harris.com>
Source record: 117510

Hello All -

For a while now, I have been making PC boards using magazine
artwork and the toner method. Now I want to make my own artwork
from a schematic. Any advice on software that will fit the bill?

Operating Environment:
1. This is a hobby effort, so cost has to be kept low
2. The boards will all be one layer, on single sided board.
3. The software can be DOS or windows-based.

Thanks. I'd like to make artwork (then boards) for some of the projects
described in "Solid State Design for the Radio Amateur".

73, gary n2jgu
gmd@rfc.comm.harris.com

A stable clean amp can be tricky at VHF/UHF, especially one with a lot of power gain per stage. If you plan to run it off 12 volts, the output impedance of the amp becomes very low as power is increased, so the matching network design becomes more critical. Tank losses can eat you alive. You'll likely be using push pull stages with single turns of silver plated heavy copper tubing as the primary with multiple turns of teflon coated line passing *through* the tubing for the secondary. You can't just substitute a heavier transistor in an existing circuit, you have to redesign the output network. You may have to redesign the input network too, but that's fairly trivial if you have several watts of drive. You can use heavy swamping for stability.

The easiest approach, however, is to do what the Japanese do in their newer mobile radios, use a hybrid power brick. These are designed to be 50 ohms in and out so matching becomes easy, and simple halfwave filters can control harmonics. They're also unconditionally stable in most cases, especially into reasonable SWR loads. However, most of these bricks only go up to about 50 watts. To get a 100 watt amp you'll need to combine two of them. A Wilkinson combiner will work.

Building medium and high power VHF/UHF amplifiers is not a good first project. Details matter in construction of these amplifiers in order to get good gain, efficiency, and stability. Construction or design errors that don't matter much at HF, or at low power, can quickly fry expensive devices. Another name for a high gain VHF/UHF power amplifier is often *oscillator*. I strongly suggest going with a proven design and following the layout to the letter until you get more experience working with these beasts.

When comparing dollars per decibel your best bet is always to put up
the best antenna you can muster. That being said, though, amplifiers
are good beginner projects and will add a bit more oomph to your
signal. You're on the right track with the Ramsey kit. Also check
out Hamtronics and Communications Concepts (among others I'm sure).
Schematics and PCB layouts can be found in the ARRL Handbook.
Switching from a 1/4 wave ground plane to a 9 element yagi/quagi/quad
will give many times more gain than an amplifier, though.
Good luck!

Use an MC10E016 to divide by 256, then use an MC10ELT21 to convert from ECL
to TTL, and then use a 74LS109 dual flip flop to divide by 4. You now have
a range of about 30 kHz. to 1 MHz. Use a frequency-to-voltage converter
as a discriminator on this signal. Analog Devices makes some
good F/V converters.

I hope some one can help with my questions:

In my car, I want to use the AM/FM antenna for my cb. I know I will have to attach the shield of the cb coax to the veh. My questions are:

Will this work (I am not looking for an great antenna, just one that would work when needed)?

Where should I attach the sheild (to the frame, body, or doesn't matter)?

I don't use the cd very often and don't want to permenately attach a cb antenna, nor do I want to use an magnetic mount. If you can help or if you know of an antenna that I might use, conntact me at:

foral@cae.wisc.edu

Thanks

Jim

I've used a DOS layout program called PCBoards, $50. There's an optional schematic capture program called SuperCad, and an autorouter called PCRoute. The latter two are $99 each. The programs are mouse aware, but can operate without one. EGA required, VGA preferred. The layout program is strictly snap to grid, but that's not a serious limitation for most things. It has good parts libraries, and you can make your own and add them to the library. There are drivers for plotters and laser printers as well as Epson dot matrix support.

You mean a receiver? But seriously, when you have that much sensitivity, you really do need some kind of frequency selectivity or you'll never be sure if the RF on the meter is the RF you're trying to "sniff." Tell us what you want it for and maybe we can be more helpful.

Unfortunately, the kind of field strength meter you are talking about would, in addition to the amplifier, need a great deal of selectivity such that it did not respond to undesired local transmitters or more powerfull distant ones. It sounds like what you really need is a small receiver with an S-Meter. At least, the complexity would be about the same.

There's a fully functional (although of limited capability; I've
forgotten what the limits are) demo of PADS available. I haven't
figured out how to do auto placing and/or auto routing from a schematic
yet, but manual placement and routing seems to work well.

##follow-up directed to sci.electronics##

I have used (not very heavily) Vamp Inc. McCad PCB-1 Design v. 4.02 and
I just got Douglas CAD/CAM Extended Layout 7.0 and do not have yet much
experience with it. Both programs are priced around $400 - $500, depending
on options.

NOTE: These are the non-professional packages. I'm not in a position to
easily spend thousands of $$ for a professional package. I just want a
reliable and easy-to-use basic PCB design program for our electronic
workshop prototype production. Both Douglas and Vamp Inc. do have
nice professional packages.

Some info on the non-professional programs:

****
Program: Douglas CAD/CAM Extended Layout 7.0 (06-Jul-92),
Print 7.0
Pen Plot 7.20 (separate product)
$395 (layout), add $125 for pen plot option

Douglas Electronics Inc.
2777 Alvarado St.
San Leandro, CA 94577
(510) 483-8770

grid size: 0.001 - 1.000 inch. Display scaling 20% to 1000%
line width: 0.001 - 0.250 inch.
pad size: 0.001 - 0.250 inch (size, hole size and shape adjustable)
hole size: 0.020 - 0.250 inch

All sizes are adjustable in steps of 0.001 inch.

Templates:

There are no ready-made IC or SMT component templates. For that purpose
you will have to build your own patterns and pads. Not a big problem, unless
you mix lots of different DIL and surface-mount components on the same
circuit.

Layers:

Component side and solder side. One or both can be visible at the same time.
- Text can be placed only on component side.

+ Customization is possible.
The basic elements are lines (rounded ends), holes and squares. A zero

length lines is a round pad. You can have a set of 7 lines, 7 squares,
7 holes, 35 pads and 35 patterns. A pad or a pattern is anything you
can create from lines, holes, squares, other pads and other patterns.

- There is no way of copying or pasting stuff from one drawing to
another one (unless you use a copy of the first one as a template).

Reliability:

I haven't used the program enough to comment on reliability.

****
Program: McCad PCB-1 Design v. 4.02 (31-May-93)
$400 - $500 for the program, pen plotter support built-in

Vamp Inc.
6753 Selma Ave.
Los Angeles, CA 90028
(213) 466-5533

grid size: 10, 20, 25, 50, 100, 125, 150, 156, 200 and 250 mils
auto-grid can be switched off.
line width: 0.007 - 0.5 inch, a set of 22 widths
pad size: 0.030 - 0.5 inch, a set of 22 pad sizes
available pad shapes are round, square, rectangular (2:1)
and elliptical (2:1).
hole size: 0.012 - 0.500, a predefined set of 22 sizes ("zero" included)

Templates: DIL for normal and surface-mounted IC:s
16 - 58 pin LCC and 28 - 56 mini flat pack SMT components
DB-9, DB-15, DB-25, DB-37 connectors
"Lines" - fill area with lines spaced at 1 grid unit
"pads" - fill area with pads placed at every grid point

Layers:

There are 9 different layers (top silk, top, top pads, inner-1, inner2,
common, bottom silk, bottom pads, bottom) and you can set the visibility
and drawing colors for each layer separately. You can also specify
multiple layers to be printed in the same printer/plotter image.

- Not customizable. Fortunately the template selection is quite large.

+ Copying and pasting between drawings is possible in McCad PCB.

Reliability:

- I have found the McCad PCB-1 v 4.04 to be a fine but unreliable program.
We have spent lots of hours and days trying to figure out ways of
circumventing different bugs in the program. The resulting PCBs from a
PostScript printer can differ quite a bit compared to pen-plotter output.
Every other time when trying to create HPGL plotter files for our PCB lab
the program crashes completely and screws up its own settings. So
we end up copying a "fresh" version of the program to the hard disk

quite often... Our problems might be related to out operating system (6.0.7 Finnish version) or equipment (mac plus, mac II) or something else. If anyone has information on these problems please tell me...

On the other hand, another lab here uses the McCad PCB ESD "professional" version with no problems. Alas, there is more than one order of magnitude difference between the prices of the McCad PCB-1 and McCad PCB ESD.

****

We have had some problems in communicating with the Vamp Inc. No such problems existed with Douglas Eletronics. Maybe Vamp was not interested in selling low-end programs.

If there is need I'll post this subjective and biased comparision of the two programs again in beginning of September after getting some experience with the Douglas package. Someone else with more experience on these non-professional programs might want to comment on this subject too. Any comments are very welcome!

Ah, how accurate do you want it? Is the input constant amplitude already?
If it is constant amplitude you can then capacitor couple it with a VERY
small capacitor and meter the output voltage. But that is TERRIBLY messy.
You could up-convert to say 4 or 5GHz and use a transmission-line
discriminator or a PLL discriminator. But that also is awkward. Nothing
simple presents itself. Maybe more details would help.

That'd be good for a frequency meter anyway. It might do gnarsties if he is
trying to demodulate things or get a "near instant" frequency determination.
We DO need more data re the application, nie?

I purchased 2 kits from RADIOKIT (New Hampshire) recently (the QRP-20
by K1BQT and the 7MHz Optimized by W7EL).
First, the 7MHz kit was missing SEVEN parts (5 caps, 1 pot, 1 resistor). After
2 attempts to get these components replaced over 2 weeks, I received
ONLY the pot. No explanation as to where the rest of the parts are.
Now for the UGLY one..... the QRP-20 kit is a mess.....missing parts,
wrong-sized standoffs for critical transistor heat sink installation,
directions furnished are for the QRP 15 (!) with several "mod sheets",
undrilled PCB connections, PCB layout errors, gross assumptions in
directions, changes in kit that were not forwarded to customers, etc.
and etc. And gee, all this fun for $100. "Easy to build ....comes with
detailed manual and parts diagram [for a different RIG]..... easy to
wind coils with _full_pictorials_ [NOT] ...." etc. etc.
This is reckless merchandising at best. I'm no rocket scientist,
but this is NOT what it was portrayed to be.

>Cheers..

Try a tv or vcr tuner. They can be tuned with a 4-30 volt source and
some can cover up to 310 Mhz or more. The if freq is dependant on
the unit so you will have to find a receiver that tunes to its if.

First of all, congrats on the new ticket. The standard simple
code-practice oscillator these days uses a 555 chip and a couple of
resistors and capacitors. You could pick up all the parts you need
(except key?) at any Radio Shack, and I'd bet they have the circuit in
one of their few books. If you key the power to the chip you'll get a
slight chirp at the beginning of each tone, which drives me nuts. You
might want to just switch on the oscillator and key the speaker lead.

If you're looking for more stuff to build, find a store that carrys ARRL
books. They have a number of books with lots of design and construction
info. They also have some files available listing parts sources. Don't
have the info handy, but I could dig it up.

Have fun,

Mike, KK6GM

>do you know of any place that sells such kits?

Congrats on the new ticket. The simplest CPO today is just a piezo-electric noisemaker, a battery, and a key. Parts available at Radio Shack. Works good, costs little. However, if you want to be able to vary the tone, you can use one of any number of single or dual transistor oscillators, or something squarewave and raspy like a 555 timer. A two transistor wien bridge feedback oscillator would be the cleanest. Circuits are in the ARRL Handbook. (You should have a copy of this book. If not, get it, but in the meantime your library should have a copy.)

If you want to be absurd, you can program an oscillator on a PC, using it's internal speaker, and key it via a key hooked to a status line on a serial or parallel port. This is actually a good introduction to realtime assembler programming on the PC. If you don't send too fast, you can even program this in Basic. :-)

1444. Painting a 1.2GHZ Antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-06-13 13:41:38 UTC
From: taylor@tix.timeplex.COM
Message-ID: <9406131341.AA01149@tix.timeplex.com>
Source record: 117633

When I was doing microwave field work, we often painted 11 Ghz
and 18 GHhz antennas for matching color of structures etc. Most
pigments are Ok. Stay away from those that have a high percentage
of metal oxides or suspended partiCLEs, e.g. metallic looking
finishes. On the Empire State Building we painted some 11.7 Ghz
6 ft. Andrew dishes including the radome cover with no measureable loss
of signal.

As I recall... The Down East antenna loop elements are all grounded... If that is the case, I see no problem in painting them.

I would avoid painting the driven element however... Painting this could cause some strange effects.

1449. Help with Antenna Rotator

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-06-13 17:58:21 UTC
From: dtiller@cscsun.rmc.edu
Message-ID: <CrCKLA.3Du@cscsun.rmc.edu>
Source record: 117639
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.antenna

I recently purchased a tower and VHF antenna system that happened to
come with a house :-) and I'd appreciate it if someone could give me a
hand figuring out the rotator. The previous owner left a control box,
but I don't think it's the correct one. By some clever sleuthing with
my ohm/inductance meter, I've found the following configuration 'up the
tower':

```
25mH 25 mH
Y/G --UUUUU---\/---UUUUU---WH/GY
/\
R/BK-------------/ \ 3 mH
| \--UUUUUU----V/BR
V
O --/\/\/\/\/\--BU
470 Ohm
```

Y/G = Yellow/Green; WH/GY = White/Gray; R/BK = Red/Black; V/BR = Violet/Brown;
O = Orange; BU = Blue

By the looks of it, there are 6 separate wires, with R/BK being ground,
V/BR being the brake, O/BL/R/BK the sense circuit, and Y/G ans WH/GY
being the actual rotator coils. The previous owner says he thinks it's
an alliance HAM IV rotator. Does the above schematic agree? What voltages/
current ratings does this rotator take? The box that was left has 8 outputs -
is it compatible, or is it to another type? (As I recall it says CDR on it -
also 'Cornell Dublier'). If it's not compatible, I'd like to make (a
computer controlled) one. I'm not up to climbing the silly thing (125 feet)
since I fell 'with' an improperly guyed tower some years ago and broke a bone
in my foot. The old courage just ain't the same :-)

Any help will be greatly appreciated, and thanks in advance,

I have been trying to give this away for some time now. Perhaps
someone will take it off my hands this time.

I have the following INSTRUCTION/OPERATORS MANUAL up for grabs:

HY-GAIN THUNDERBIRD (TH3Mk30 THREE ELEMENT HAM ANTENNA.

This INSTRUCTION/OPERATORS MANUAL is in good condition.

The intent is to give this INSTRUCTION/OPERATOR MANUAL to an
individual or entity who ACTUALLY has the equipment.

The first person to send me e-mail and follow up with a large manila
SASE with postage for 3 ounces gets the prise.

If you are the lucky one, you will be asked to send a SASE (large
manila or other envelope) with the appropriate amount of U.S. postage
to me c/o the address in my .sig file.

Also, as a courtesy, a photocopy of the manual will be sent to anyone
else who sends me a SASE.

Good luck to one and all.

Hi Dave, I have 1 piece of info on you rotator...

It's an AC phase reversible motor. We played with one of these for days at
Gateway Tech before figuring out how to make it run.

```
25mH 25 mH
Y/G --UUUUU---\/---UUUUU---WH/GY
/\
R/BK-------------/ \ 3 mH
| \--UUUUUU----V/BR
V
O --/\/\/\/\/\--BU
470 Ohm
```

Y/G = Yellow/Green; WH/GY = White/Gray; R/BK = Red/Black; V/BR = Violet/Brown;
O = Orange; BU = Blue

By the looks of it, there are 6 separate wires, with R/BK being ground,
V/BR being the brake, O/BL/R/BK the sense circuit, and Y/G ans WH/GY
being the actual rotator coils.

To make the motor spin, we used 12vac connected as follows:

ac1 to R/BK (common)

ac2 to Y/G (coil 1)

ac2 through 50uf non pol cap to WH/GY (coil 2)

to reverse direction just switch which coil gets the cap.

I have seen several of these motors, and all have operated on the same principle
of phase lead/lag to make it spin.

I would expect that nearly any rotator would work it provided that the voltage
was same. I have seen a rotor box that had a 24v filament type transformer that
powered it.

Hope this info is of use.

From: little@iamu.chi.dec.com
Message-ID: <2tjhos$ii7@nntpd.lkg.dec.com>
Source record: 117647

I'm building transverters for 903 MHz and 1296 MHz and wondering whether I can use some coaxial relays I picked up at a hamfest for use in T/R switching at low power. They are instrumentation relays from the looks of them, i.e. square boxes with BNC connectors, reed relays inside, and apparently terminated when not powered into a 75 ohm resistive load (according to my trusty multimeter.) I'm assuming they won't handle more than a few watts, but for now that's OK with me. My concern is that they are probably 75 ohm impedence based upon the 75 ohm termination and that they probably came out of some piece of instrumentation where 75 ohms is the norm.

The only real information I have is from a label which indicates they were supplied by R.F. Components, Hoddesdon, Herts, England, model number is A4202.02.28D.82.04. Also from trying them out, they appear to have 12V coils, and be configured as 2 SPST relays sharing the normally open contact.

Will the 50/75 ohm mismatch cause much problem for something like the NEC monolithic power amps such as the SC1043? Also, what's the likely power handling capability of such a relay?

I am loking for the schematichs diagram and the component view of
the 2 meter RTX named IC02E from ICOM.

It is a 1974 (I guess) 2 meters RTX.

The problem is in the receive section.
Basically it is ok but it need 10 microVolt at the antenna input
in order to receive something.
It should usually be 0.5 microVolt .
I checked this with a R.F. signal gererator.

I do not know if it has an RX preamplifier or what else that can went
bad.

I will really appreciate the schematics but even hits.

please email me at robertov@hqlab.ico.olivetti.com

If anybody is so kind to send me xerox of schematichs and eventualy
components view i can refund his/her money if he/she want to.

It will cost you one dollar for the letter

I am selling a homebrew 40 meter cw transciever. It covers 7.000-7.075
and about 7.100 - 7.175 mhz, puts out about 2 watts. The receiver is a
direct conversion type, but uses very good audio filtering.

The rig was based on the article in August 1980 issue of QST by W7EL and
improved with better double tuned band pass filter and a chebychev filter in
front of the audio preamp.

I am also selling a 65 Watt computer power supply (I believe it came out of an
XT).

Any inquiries, please email to bad1679@ultb.isc.rit.edu

Thanks..

I've found a couple of sources:

Newark electronics sells them individually for $2.21 ea, 1.95 in 100's
call 1-800-298-3133 x48 for a catalog and info.

Penstock also has them, but only in lots of 100, for @2.00 ea
call 1-408-730-0300 They will also send you an HP catalog if you
ask.

I'm looking for the chip capacitor version of the 3081, called the HPND-0002.
Penstock has them, but again only in 100 lots - Anyone interested in getting
together on an order?

1466. Ideas for 100Hz-100KHz HV xfmr?

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-06-14 17:39:38 UTC
From: matthews@ac.wfu.edu
Message-ID: <2tkq0q$3dm@quad.wfunet.wfu.edu>
Source record: 117654

I need an audio (100 Hz -100 KHz) transformer with a secondary that
can go to around 1000 volts. Current is very low, less than 1 mA.

I'm actually using this to apply an alternating electric field to
a small crystal for an experiment I want to do.

Any ideas? Any suggestions for something off the shelf, or if not
what I should worry about in winding my own?

I might be able to get by using a different approach with a 400 volt
secondary.

Thanks for your help.

Not going to mention any callsigns or names but RadioKit was founded by a
very nice couple who are well known in amateur circles in NE and all over.
They no longer own it and the present owner does not seem to be interested
in providing the level of service and quality that was originally there
under the earlier mangement. In fact the previous owners are disappointed
with how things are being presently handled. Thats all I will say except
this should be a wake-up call to the present owner.

Hello All -

I can't speak about RadioKit kits, but I sent money for a catalog
a year ago and never received it. From what was posted on the Internet
back then, I wasn't the only one. I talked to the owner while
at Dayton this year. I inquired about getting a catalog, so that I
might be able to purchase some parts. Well, he said they were out. I
asked how then might I order parts (read, how can I send you money,
so that you might profit from it) and his reply was that maybe I could
get together with someone in my area and use their catalog.

Enough said. I will only twist a person's arm so hard, in order
for them to take my money for goods and/or services.

73, gary n2jgu
p.s. try dan's small parts and kits,
624 kits,
oak hills research,
mouser
I have ordered mucho stuff from all the above and have never
felt cheated or ignored. In fact, dan's has the nn1g superhet
on sale for $40 (everything but case)... a good deal for someone
with intermediate building skills.

The concerns you have are real enough, but the one you've forgotten
is the isolation between the poles. If you have 30db isolation and you're
running 10W, then 10mW will be coming into your receiver front end. I think
that's near the limit for a FET (someone else may know better). If it's
an instrumentation relay, it may only be good at HF. At 1Ghz it may have
no isolation. Having a relay that's not resistive at 1Ghz will cause
more problems than you'll ever want to know about even if it is 75ohms
rather than 50ohms. Either buy one that's known to be OK, or measure the
one you have on a network analyser.

Source record: 117419

A friend is having trouble with sheep rustling - he's has about 70 stolen this summer so far. The local Police won't do anything unless we can tell them who's taking the sheep!

We were thinking of radio tracking to find out where they're going, but there's a few problems.
1. The sheep-mounted bit must be very, very, small and have an invisible antenna.
2. Need a battery life of about ten weeks
3. Range of about 30 miles in hilly terrain
4. The sheep bit must be cheap enough to be disposable
5. The sheep are going missing from a piece of land wityh no obvious gates, so they can't be sent through any sort of localised security gate.
6. The animals may be transported in an aluminium trailer!

I've been thinking of a transponder on the sheep, and a directional tracker, but I shudder at the thought of building such beasties!

Anyone with any thoughts? Anyone experienced this problem before? and solved it?

Thanks

Richard Smith (richard@mole.demon.co.uk)

> Is there such a thing as a kit to build a tube receiver

Menachem, if you don't find one and want a good reference book
for building your own tube receiver, let me know by email.

Finding the parts can be a real bear, especially if you cant
get to a ham radio flea market or know old codger with an extensive
junk box (and to think when I was a lad I had all that stuff too,
tubes, sockets, coils, switches and air-variable caps by the truckloads!)

I just saw a book at Tower Record Bookstore that had to do with
building tube radios...most of them I saw used dry cells for B+ and
bias. Most of the circuits looked like low plate voltages..much safer
believe me... I built a two-tube regenerative radio with 450VDC B+
when I was a kid... unfortunately, the headphones were in series with
B+ and the cables were frayed...needless to say, I contacted the B+
at the ear and got knocked off my chair and landed about 6 feet away
on the floor. I have a real respect for that B+ jive! I forgot
the title of the book, but I can get it for you, ok?

Glad to see you are interested in tubes....they sure bring back a
lot of memories...

I recently picked up an old Boonton model 190A Q meter. This is the VHF version, covering something like 20 to 260 MHz. Does anyone have any information on it? It seems to work OK, but operating instructions would still be helpful, even though it's easy enough to figure out for the most part. How about a schematic? That would be really appreciated!

I used to subscribe to midnite engineering...It was good at times but not consistently enough for me to renew...I was interested in it for it entrepreneureal,(where's my spelling checker when I need it), articles when I was running a side consulting business....And at the time it was only quarterly.

I think they have it at our local bookstore if you want I can pick up a copy fer ya.

There is a conformal coating avaable from RS and Farnell in the UK. If you need exact type, mail me directly. Anyway, it is said to have good dielectric properties. To get the best from it, you need to bake at ~200 deg C for a couple of hours. I did intend using it to increase the working voltage of an air-spaced cap at 144MHz once. I must have been satisfied it would be okay at that frequency anyway. As a matter of interest, it is said to withstand an E field of 50kV/mm.

This isn't trival if the bandpass has to be flat over that span.
Ordinary iron core modulation transformers only go up to about
20 kHz before hysteresis losses and interturn capacitance causes
response to roll off. Most ferrite core designs don't cover the
low end well. So, another approach might be better, such as a
capacitance coupled circuit. A single pole would give a 3 db
per octave rolloff, but suitable RC multi-pole designs could
give a flat response. Better still would be a direct coupled
push pull active design using tubes that can tolerate 1000 VAC
without flashing over.

If you don't need flat response, most any filament transformer
can be pressed into service as a modulation transformer. Their
voltage rating is generally sufficient to tolerate 1000 VDC
at low current.

Changes: new mailing lists, .packet rmgroup, and .policy updates

(Note: The following is reprinted with the permission of the author.)

This message describes the rec.radio.amateur.*, rec.radio.cb, rec.radio.info,
and rec.radio.swap newsgroups. It is intended to serve as a guide for the new
reader on what to find where. Questions and comments may be directed to the
author, Jay Maynard, K5ZC, by Internet electronic mail at
jmaynard@oac.hsc.uth.tmc.edu. This message was last changed on 18 September
1993 to add the mailing lists for the new rec.radio.amateur newsgroups, to
note the rmgroup of rec.radio.amateur.packet, and to officially retire some
(in)famous threads of discussion on rec.radio.amateur.policy.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list
for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions
were held on the mailing list, and sent to the mailboxes of those who had
signed up for it. When the Usenet software was created, and net news as we
now know it was developed, a newsgroup was created for hams: net.ham-radio.
The mailing list and the newsgroup were gatewayed together, eventually.

As the net grew, and as packet radio came into vogue, packet discussion began
to dominate other topics in the group and on the list. This resulted in the
logical solution: a group was created to hold the packet discussion, and
another corresponding mailing list was created as well: net.ham-radio.packet
and PACKET-RADIO, respectively.

These two groups served for several years, and went through Usenet's Great
Renaming essentially unchanged, moving from net.ham-radio[.packet] to
rec.ham-radio[.packet]. Readership and volume grew with the rest of the
network.

The INFO-HAMS mailing list was originally run from a US Army computer at
White Sands Missile Range, SIMTEL20. There were few problems with this
arrangement, but one was that the system was not supposed to be used for
commercial purposes. Since one of hams' favorite pastimes is swapping
gear, it was natural for hams to post messages about equipment for sale
to INFO-HAMS/rec.ham-radio. This ran afoul of SIMTEL20's no-commercial-use
restriction, and after some argument, a group was created specifically
```

for messages like that: rec.ham-radio.swap. This group wasn't gatewayed to a mailing list, thus avoiding problems.

While all this was happening, other folks wanted to discuss other aspects of the world of radio than the personal communications services. Those folks created the rec.radio.shortwave and rec.radio.noncomm newsgroups, and established the precedent of the rec.radio.* hierarchy, which in turn reflected Usenet's overall trend toward a hierarchical name structure.

The debate between proponents of a no-code ham radio license and its opponents grew fierce and voluminous in late 1989 and 1990. Eventually, both sides grew weary of the debate, and those who had not been involved even more so. A proposal for a newsgroup dedicated to licensing issues failed. A later proposal was made for a group that would cover the many recurring legal issues discussions. During discussion of the latter proposal, it became clear that it would be desirable to fit the ham radio groups under the rec.radio.* hierarchy. A full-blown reorganization was passed by Usenet voters in January 1991, leading to the overall structure we now use.

After the reorganization, more and more regular information postings began to appear, and were spread out across the various groups in rec.radio.*. Taking the successful example of the news.answers group, where informational postings from across the net are sent, the group rec.radio.info was created in December, 1992, with Mark Salyzyn, VE6MGS, initially serving as moderator.

In January, 1993, many users started complaining about the volume in rec.radio.amateur.misc. This led to a discussion about a second reorganization, which sparked the creation of a mailing list by Ian Kluft, KD6EUI. This list, which was eventually joined by many of the most prolific posters to the ham radio groups, came up with a proposal to add 11 groups to the rec.radio.amateur hierarchy in April 1993. The subsequent vote, held in May and early June, approved the creation of five groups: rec.radio.amateur.digital.misc (to replace .packet), .equipment, .homebrew, .antenna, and .space.

The Current Groups

I can hear you asking, "OK, so this is all neat history, but what does it have to do with me now?" The answer is that the history of each group has a direct bearing on what the group is used for, and what's considered appropriate where.

The easy one is rec.radio.amateur.misc. It is what rec.ham-radio was renamed to during the reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize

this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, should be removed by September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is now rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there.

The first reorganization added two groups to the list, one of which is rec.radio.amateur.policy. This group was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The other added group is rec.radio.cb. This is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently Mark Salyzyn, VE6MGS. The email address for submissions to the group is rec-radio-info@ve6mgs.ampr.ab.ca. Inquires and other administrivia should be directed to rec-radio-request@ve6mgs.ampr.ab.ca. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups rec.radio.amateur.antenna, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas,

commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

A Few Words on Crossposting
===========================

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

There is a magazine (actually, more of a newsletter) called Lowfr. I don't
have the address, but if you send me e-mail, I can go look for the address.
If you're interested in QRP also (a lot of lowfers seem to be), there is
a company called 624 Kits that makes QRP and lowfer kits.

We have an SFU-455B ceramic filter from Radio Shack.
It has been installed in a tube circuit in the IF chain.

There seems to be an impedance matching problem. We are looking for the
input and output impedance specifications.

The input to the filter is being driven from the one IF transformer output.
The output of the filter is driving the input of a pentode.

Thank you in advance for any help you can give.

One good place for current LowFER information is from the Longwave Club of America (LWCA) at 45 Wildflower Road, Levittown, PA 19057.

They'd appreciate it if you were to send an SASE when you request information.

This club has been active since the middle-early 70's and it specializes it those things below 500 KHz (well, below the AM BCB, anyway...)

Often, they carry information on most any aspect of low frequency stuff, from propagation, to NDB monitoring, to construction articles, to whatever. Several years ago, they had a great series of articles on "The Sounds of Natural Radio" which covered whistlers, "tweets", and other spherics... as well as "Earth Currents"...

There have been other informal newsletters from time-to-time, but as with other things, they ebb and flow depending on critical mass, free time of those involved, etc.

One thing about LowFER communications: I found it to be very much like moonbounce in many ways in that you are always fighting some pretty horrid SNR's, etc. One thing, though: A properly-equipped pair of transmit-receive stations should consistantly have >700 mile groundwave coverage (daytime...) The Utah-California path was pretty consistant. Of course, you need to take great pains to assure this (The TX had a phenomenally effeicient antenna system (approaching 1%!!!) and the RX station had a monsterous receive antenna, and was 8 miles from the nearest powerline...) but "normal" people (with "normal" installations) were able to copy him as well very frequently using CW... My best DX was hearing 9HDQ (Indiana) when I lived in Flagstaff, AZ, using active whip and my TR-7 with a 1.8 KHz SSB filter... Pretty good signals from all around, that night...

Wouldn't it be easier to put some kind of electronic perimeter fence (laser, capacitive, siesmic) and just go tearing out there with you Uzi in hand, instead? With the constraints you've placed on the transmitter, current technology is not going to be cost effective. Another option may be to use some kind of infrared cameras and a VCR. Only problem with this is that sheep are going to show up. Maybe wire a couple of the sheep with 5 pounds of C-4 with a radio receiver, and if the carrier ever drops, *KABOOM*. No more sheep, no more sheep rustler...

One problem would be is that all the animals would require transmitters.
We have a local company that has developed marking devices for animals. The
device is inserted under the skin of the animal and can be electronically
detected. So you would always be able to identify your animals. The company
name is : Destron-IDI, 2995 Wilderness Pl., Boulder, Colorado, 80302

I am considering going for my amateur licence soon, and was wondering if anyone on the echo knows of any circuits that have been published in the electronics/amateur magazines for a reasonably easy to build low power AM/SSB transmitter (something like 15 or 20 watts, to build up while studying for the course). Solid state would be preferable to valves.
Any help would be appreciated.

Thanks, Bill.

Obvious solutions to Americans, but Richard isn't in a free country. He can't just deal with the rustlers without the jackboots of authority coming down on him.

I think a pulse transmitter is going to be the best bet. Peak power can be high enough to be detected at a distance but average power would be low enough to allow for decent battery life. A two FET circuit with one FET acting as a timer/switch and the other as the switched oscillator should do. I like the idea of the C4 better though. :-)

>*KABOOM*. No more sheep, no more sheep rustler...

Hmmm. Problem is the perimeter is about five miles long, changes elevation by about 500 feet, goes through woods and streams and the sheep could be going through *any* section of it. Then it's about eight miles of narrow, twisty road from my friends farmhouse to the land where the sheep are. All this kinda rules out perimeter guards or IR cameras.

The last solution maybe an answer, though ;->

Cheers

Source record: 117433
Cross-posted to: rec.radio.amateur.misc,sci.electronics,rec.radio.amateur.homebrew

I am interested in information about Rayovac "Renewal" reusable alkaline batteries.

They look like a good deal, since the batteries themselves are similar in cost to ordinary alkalines, and unlike other rechargables have the full capacity of an alkaline battery , at least for the first few times the battery is reused.

Does anyone have experience with them or understand how they work? Is it possible to charge them yourselves, or are the specs for doing so being kept quiet by the manufacturer?

Hi,

Sorry if this is a stupid question. I am new and very interested in scanners.
I was just wondering if it is possible to assemble/"make" a scanner
from scratch - I mean going to the electrical shop to buy those transistors,
diodes, etc and assemble it up.

If it is possible, is there a guideline outhere where I can download.

Thanks.

The HP 3081 PIN diodes turn on full(lowest resistance)

with 100 ma of current thru them....I advise that users

look at the data sheet before spending the bucks...

10 ma will also work but you will have more insertion

loss and poorer intermod response then 100 ma.

>diodes, etc and assemble it up.

Sure it's possible. A friend of mine builds live steam locomotives in
his basement. Anything is possible to build if you put enough effort
into it. A better question is whether it's practical. Today's scanners
use custom chips that you aren't going to find at the local parts store.
To replace those in your design, you're going to have to use a lot more
discrete logic and a general purpose microprocessor that you program
with the desired scanning algorithms, if you want your scanner to work
like commercial scanners. (You can make an analog scanner with swept
oscillators like those of 20-30 years ago, but I doubt that's what you
want.)

A scanner is nothing more than a wide range receiver that can
automatically tune itself and stop when it detects a signal.
That part is easy. Receivers aren't hard to build, and automatically
tunable oscillators aren't hard to build (typically a programmable
synthesizer in modern scanners, though some still use switched crystal
oscillators). The circuit for stopping on the center frequency of a
detected signal is a little tricky, but not hard either. What becomes
harder are the programmable functions of modern scanners. Commercial
scanners use custom microcontrollers to do that. You'll have to build
a small computer and program it to do the same things. (You can interface
a receiver to an existing computer, like the PC, and do the programming
there, but usually you'll want to use one of the single chip field
programmable controllers on the market.)

If you want features not available on commercial scanners, then you
will have to build your own. But if you are satisfied with the features
of existing commerical scanners, their low price means anything you
build will cost more, and take much more time to do, than it's likely
worth.

My humble and personal opinion:

They are not suited well for amateur use. They have a relatively
short cycle life (25 cycles), with degrading capacity after
5 cycles. The internal impedance is quite high, so that if
you count on them to supply 1A of power, the terminal voltage
will fall significantly. They have a sloping discharge characteristic,
so the last 50% of the cell capacity is supplied at 1.15V and less.
They can't be quick charged.

They are probably OK, for occasional use, where you may want to
use alkalines in the first place. But, for everyday cycling
use, get NiCds.

I looked at the Tandy TRC-503 (I think). 5 sythesized channels, undoubtably made by Maxon, like the HTX-202, and I concluded that moving it from the designed frequencies was a pain in the butt. The biggest problem would be the fact that the 10.24MHz crystal used for the PLL reference timebase is also used as the 2nd LO injection; changing this changes the 2nd LO offset, which probably makes the radio pretty deaf. Erik Sorgatz posted some notes suggesting success in converting these exact radios, but I'm pretty dubious myself.

Good luck!

And after 25 re-charges they have degraded to *only as much*
capacity as a nicad has. The roll-off of voltage gives you some
indication that your batteries are dying, so you can finish a
conversation before replacing them. You can leave them in a scanner
for several months, and still expect them to be darned near to fully
functional when you need it. They don't develop internal shorts that
make you think your pack is charged but it dies instantly when you use
it.
The down side is they ain't worth squat in high-current
applications. If you *must* ALWAYS run your HT on the highest power
setting, these are not for you. I've had very good luck with them in
a DJ-580 on medium and low power, even accidentally leaving it on
overnight *after* heavy use that day, and it was still working the
next day.
They cannot be quick-charged (which tends to mean an early grave
for ni-cads if done often).
Many rigs can charge the ni-cads while running off of 12 volts from
the car. Renewals won't do this.

I'd say they would work well for amateur radio, given that you live
with the FCC regs requiring *only as much power as necessary for the
desired communications*.

There are lots of tube circuits in the older Radio Amateur Handbooks. I have a '64 edition that is loaded. No - I won't part with it:) I've seen this kind of stuff for sale at hamfests though. Also a good place to find the parts. I even still have some receiving tubes, caps, and a few 125V/6.3V transformers around.

How BIG is the "ranch" . . . i.e. might one construct a tall "watch tower" that can be used to observe the entire estate?

If so, perhaps a more robust scheme would be to build said watch tower, buy a high-power quick-fire riffle with a night-vision scope on it, buy a big coffee pot, and hire a few of the local gun-nuts to stand watch. When they see someone stealing the sheep they pick-off the thieves with a few rounds. You simply load the dead/wounded bodies into the back of an old pick-up truck and drop them off at the doorstep of the local cop who is too lazy to do his job. I think after one of these episodes any further sheep-stealing will be done at someone ELSEs ranch!

Welcome to the hobby, Rod! Pick up any edition of _The ARRL Handbook_ within the past 15 years and you'll find all sorts of good code practice oscillator circuits that are small, inexpensive, fun to build, and easy to work with. Most of them use a 555 integrated circuit that you can get at Radio Shack (if you can survive their inflated prices for everything).
Radio Shack is still a great place to start. It worked for me. The BEST thing to do is get a copy of their book, "Getting Started in Electronics" by Forrest Mims III. It's a wonderful starter manual for folks who want to find out what electronics is all about. It does not cover anything in ham radio, but tells you what all the parts do and provides over 100 circuits that you can easily build. This is the book that got me started. It's a large green paperback, all written by hand, and costs just a couple of bucks. Indulge yourself and you'll never regret it.

I've often thought it would be kinda neat to do the following:

1) Set-up a perimeter fence with a hi-powered (i.e. industrial metal-cutting) laser.

2) Design a control system that would operate the laser in a pulsed (i.e. PWM'd) fashion at some rediculously LOW duty cycle (like .1%) so that it can be detected by a standard IR phototransistor.

3) When something breaks the beam (i.e. someone walking into/outof the protected zone) the controller would crank-up the duty cycle to 100% for a 1 second period.

4) Pfffffffft . . . no more intruder.

It seems to me that Minicircuits has published information on DC ratings.
Instead of calling them, look thru all their literature. (I haven't
had much luck calling them with technical questions).
In any case, you shouldn't have any trouble if you're only running 10 or
15 mA. thru the windings.

That's a good question. First of all, according to MCL's data sheet on the SBL-1, both the RF and the LO inputs connect to a winding of a transformer (no doubt wound on a toroid). The wire used is probably fairly large (28-32 gauge) so there's no real concern about current handling. There is a question about what RF of LO current will cause saturation in the transformers.

The data sheet only says that the absolute max RF or LO power is 50 mW and that the absolute max IF peak current is 40 mA. I'm guessing the IF current restriction is to protect the diodes. So, looking at the RF/LO restriction, 50 mW corresponds to about 32 mA RMS, or 45 mA peak. Since MCL won't give you any better info, my guess is to design your circuit such that the peak current through the RF pin or the LO pin won't exceed 45 mA. In your case, that would be your 15 mADC plus the peak signal current.

: batteries.
[...]
: Does anyone have experience with them or understand how they work? Is
: it possible to charge them yourselves, or are the specs for doing so
: being kept quiet by the manufacturer?

I've been using them since they first hit the market. One major problem is that the AA size is only rated at 700mA peak current, and the typical HT pulls a little over 1A at high power xmit. My experience is that this _significantly_ cuts down on the power output from an HT. However, if you are using an HT to mostly monitor (mine pulls about 60mA with squelch closed, about 120mA with squelch open at full volume), they work fine.

They have very low self-discharge rate. Ray-O-Vac claims 5 yrs, but I haven't measured it (yet ;-).

Occasionally you'll run into a cell that the charger "never turns off" for. Also, the recharge times in the literature seem pretty optomistic, at least in my experience. (5 hours is the stated time for AA, but mine often take nearly a day.)

The literature implies that the charger pulses the cells at 120Hz (gee... wonder how they generate that! ;-) and measures the voltage between pulses, shutting off when the cells are fully charged.

Every pack of them has an 800 number you can call. Ask them to send you the data sheets. (Sorry, I don't have the number here.)

My recommendation is that they are good for places where a typical NiCd would last at least 5 hours _under worst conditions_ (like with the xmit button down at high power - so the typical HT is not a good candidate), and where the typical alkaline battery would last less than 1 year of "normal" service. (If it lasts longer than 1 year, probably cheaper to just use normal alks.)

My biggest complaint is that they aren't available in the 9V size - I've got a lot of applications where a 9V Renewal would be ideal. (Due to the need to control each cell's charge separately, don't hold your breath on seeing one soon, either.)

My only connection with Ray-O-Vac is as a (fairly) satisfied customer. ;-)

Clark

According to Rayovac, who replaced several of my cells for this problem,
the early batches were prone to develop internal shorts after a few
cycles. Send them back.

>The literature implies that the charger pulses the cells at 120Hz (gee...
>wonder how they generate that! ;-) and measures the voltage between pulses,
>shutting off when the cells are fully charged.

Actually it varies the duty cycle from about 70% (if I remember) down to
zero as the voltage rises. When the duty cycle falls to 25% the LED goes
out. However, since the big and small chargers have different peak
current, a 25% duty cycle will deliver different amounts of current when
the light goes out. The only way you'll get full capacity after removing
the cells immediately after the light goes out, is to use the big charger
only for C and D cells. If you charge Aa/AAA's leave them in overnight.

If memory serves, these things have an impedance of around 300 ohms.You'd probably need to use the tapped IF transformers commonly found in older transistor radios. Don't know if they can take tube voltages though.

If this is a Murata/Erie IF filter, they usually have Zin/out in the 1.5K to 2.0K range. I'll have to look it up...

Source record: 117467

I am putting together a VHF/UHF directional coupler. I plan to use it at first on 2m, but I would like it to work up to 1.2GHz. I have used 1N34A's at 2 meters before with some success, but I doubt that they will work at much higher freqs. Can someone suggest a good diode to use in the low-gigahertz range? Preferably something with a low Vf like a Schottky, though Vf up to 0.4 V or so is probably ok.

TNX and 73

Message-ID: <1994Jun18.113453.1@ccsvax.sfasu.edu>
Source record: 117268

Yet another dumb question from a boatanchor era ham trying to enter the late 20th:

I notice modern HF receivers (or at least the one I just ordered from Index Labs) use UPconversion. The IF in the Index Labs unit, for example, is 50mhz. This clerly creates a favorable image ratio, but in former times would havee been rejected because a) it's hard to generate IF selectivity at that frequency, and the alterative of filtering at AF has its own problems, and b) it's hard to do needed, stable amplification at that frequency.

Obviously these problems have been overcome, because the upconversion systems are getting good reviews, but I wonder if someone can tell my just what technological developments have made this new architecture possible.
For example, the Index Lab RX uses SCAF filters. Are they immune to the intermod and other problems usually associated with audio filters? If so, how so?

(Interestingly, none of the fairly recent ARRL publications I have, including LAST years -- not this year's -- copy of the handbook, is of any use at all. Is the technology changing that fast? Or is the Handbook just in need of a major revision? Or did I just overlook what's actually right there in front of me?)

Thanks much!
Jim

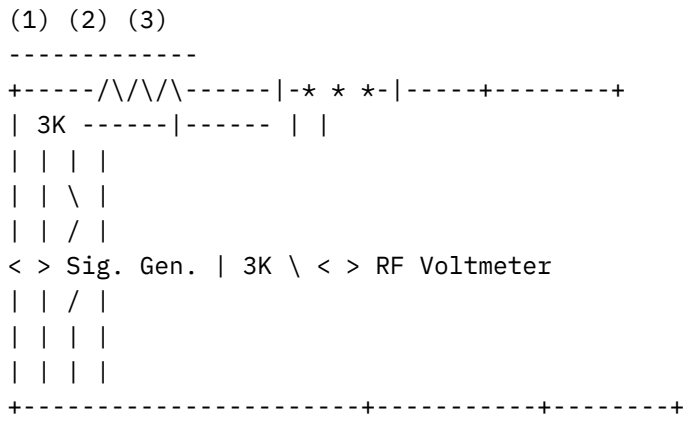
From my Murata/Erie catalog...

Model SFU455B (connected to an I.F.T.)
Center Freq 462 +/- 2 KHz
3db BW 10 +/- 3 KHz
Ripple (db max) -
Selectivity (db min) 4 @ +10 KHz / 6 @ -10 KHz
Termination Impedance 3 K-ohm
Spurious Response (db min) 10 (1-3 MHz)
Insertion Loss (db max) 5
Operating Temp Range -10C - +80C
Withstanding Voltage 50 VDC

The schematic for the test circuit ...



Hope this helps...

Certainly! As a licensed ham, you are authorized to build your own
transmitting equipment out of anything whatsoever (including other
kinds of transmitters).

There are some further requirements for commercially marketed equipment,
but not homebuilt equipment.

That is true - as far as he goes. Converting a 49MHz HT to 440MHz would be one HECK of a job, though. It is MUCH more than changing a crystal and antenna. It would amount to removing the guts of the radio and rebuilding everything but the case and knobs.

From: hirschj@vax2.concordia.ca
Message-ID: <19JUN199410154511@vax2.concordia.ca>
Source record: 117277

I recently acquired an old Regency crystal controlled 10-channel
scanner at a ham fest. The only other ID markings are stamped on the
case (#204-c26951). has anyone out there heard of this/have docs
for this? The unit has 8 of the channels with crystals and 2
without. Each crystal socket has 3 pin inputs...it does not seem
to make a difference whether I insert the crystal into pin inserts
1 and 2 or 2 and 3. There are also 3 antenna inputs; 2 that
look like car radio plugs and 1 that looks like twin-lead screw
terminals. Again it does not seem to make a difference which
one I use. Finally there are two holes in the top of the case
which look like openings for antenna whips; one is 1/4 inch
in diameter and the other is half that. The unit works so I
want to play with it (the price was $4 so I couldn't resist).
Any help or advice would be much appreciated.
Thanks,
Jack

It's legal to convert *any* radio, or build one from scratch for that
matter, into the amateur bands as long as the result meets the standards
of good amateur practice in regards spurious emissions. However, the
only *practical* ham band to convert a 49 MHz HT to is 6 meters. You'd
practically have to rebuild it from scratch to make it work right at
70 cm. They make dandy little 6 meter rigs though, and the conversion
is usually easy.

Congrats on the ticket! Yes, you can legally convert radio gear to operate
in the ham bands legally, as long as the transmissions meet the spurious
spec's set forth. The best you can expect from the 49Mhz HT is moving it up
to the 6 meter area. You may want to build an outboard solid state amp
too, unless you can get it to work on a nearby repeater. 440Mhz is way out
of it's intended design, so I wouldn't ,ake that my priority. Good luck!

There is a simple and cheap solution to this. Go to a trendy designer store such as "Cost Plus" or "Pier One", the sort of place that sells wicker chairs and cheap china. They often sell empty biscuit tins with cute pictures of cats on them. They come in many sizes and shapes, they are tinned for easy soldering.

The other source source of biscuit (sorry cookie U.S.) tins is oriental grocery stores. They sell biscuits in wonderful square tins. Try the durian cookies for a truly different experience. The cookies are cheap and tasty, the tins are free. I have also picked up aluminium "sandwich boxes" at oriental grocery stores. These are an RF tight aluminium box - would cost about $30.00 if they were sold for RF rather than lunch.

If you don't think having your stuff in a tin with pictures on it is "professional" (The correct term is "businesslike") then paint it in a trendy designer pastel or tiresome engineering blue/grey.

As a ham, you can use any equipment you want, as long as it meets all
the Part 97 specs for the band and mode you're using. If you want to
convert an old TV into a 2m tranceiver, it's legal (not feasible, but
legal!). The only legal problem comes with trying to go the other
way, using ham gear on non-ham frequencies.

As for converting 49MHz walkies, some people are converting them to 6m
(50-54MHz), but you're not going to get it up to 440. That's far too
large a jump.

Forunately for me, there are a couple surplus electronics parts stores here in the rochester ny area, so cheap project boxes are available.

I have used printed circuit board material to make enclosures too. The Doug DeMaw (w1fb) qrp books describe this method. I use my table saw to cut the board to size, then solder the box together. A lot of my projects use plexiglass for a top, so you can see all the goodies inside. Yes, in some cases hand capacitance can play into operation of the radio, so be careful about using a plastic lid. Anyway, I pay 2 cents per square inch of single sided board, so the enclosure price is low. I also have a small aluminum break (sp?) on order from harbor freight (left coast import tool company), so I can get sheet aluminum and form cases that way (i.e. nice 90 degree angles, smooth bends).

: Could someone clue me in to the formula for calculating the characteristic
: impedance of a coaxial transmission line with a square shield, ie the cross

From "Reference Data for Engineers," seventh edition, Howard Sams, given
that D is the box inside side length and d is the inner conductor diameter,

Zo approx= [138*log(rho)+6.48-2.34*A-0.48*B-0.12*C]/(epsilon)^0.5

where epsilon is the relative dielectric constant,

rho = D/d

A = (1+0.405*rho^-4)/(1-0.405*rho^-4)

B = (1+0.163*rho^-8)/(1-0.163*rho^-8)

C = (1+0.067*rho^-12)/(1-0.067*rho^-12)

Well, you asked for it...

There are also formuale for a single wire in a trough, and a single wire
centered between two parallel ground planes.

Build a 2 GHz. grounded emitter amplifier using a transistor with an
Ft of 5 GHz. or so. (MRF951 will work fine) Now connect the
cathode of a Toshiba 1SV186 tuning diode (available from Matcom,
Palo Alto, CA) to the collector, which should be connected to
VCC with an RF choke. The anode of the tuning diode is coupled
via a 100 pF. capacitor to the base. This junction also has a 1 K resistor
to feed in the tuning voltage, which is relative to VCC. The leads of the
diode are the tuning inductance; adjust lead length to get the
right frequency range. You should be able to get about an octave.
Be sure to use at least 5 DC volts across the emitter bias resistor
(which of course is RF bypassed) to assure stable bias across the tuning
range. Put a 50 ohm load impedance on the collector and no load on
the base.

Message-ID: <2u6phf$mfa@nyheter.chalmers.se>
Source record: 117295
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics

I am interested in wireless communication for networking to a building ca 500 meters away. I have seen the "Multi Megabaud Microwave Link"-project in ARRL's handbook, and find it most interesting. Has anyone on the net actually built one?

The alternative, as I've understood, is setting up a laser link. How hard is such a beast to build? Has it been done? What kind of costs are we talking about?

I have heard rumours that the ARRL handbook project it is due to be (or has already been) updated from 2 Mbits to 10 Mbits. I have only looked into the '93 version, so I wonder if this is true?

Finally, are there any other ways, not necessarily as fast? Preferrably not "ordinary" radio, because frequencies are hard to get.

Suggestions anyone?

An empirical approximate for this type of calculation is to do the calculation
for a round cable but multiply the diameter by a factor of 1.2. This comes
pretty close in practice. The formulae for the round cable calculations can
be found in any electomagnetics textbook. Also, the ARRL handbook has a little
blurb on helical resonators which also touches on the topic.

>

The biggest advantage in up-converting to the first IF is that you can design a general coverage receiver with at least the first IF outside of the frequency coverage, and a single low-pass filter is all that is needed for IF image rejection (more filters are needed for IM rejection though). General coverage is very important in todays market.

The selectivity is not as much of an issue as it used to be because of (relatively) low cost crystal and SAW filters at the high first IF frequency. The amplifiers at 50MHz are not too much of a problem.

There has been a lot of progress in building low-cost high-volume high-frequency amplifiers and filters in the last 10 years with the booms, first in satellite receivers, then in cellular and cordless phones.

Meaning, I think, no tuned circuit on the input (grid)...
For AB1, it's ok. However, if you ever draw any grid current (class AB2 or B or C), gotta use that tuned input. Just a Q of 2 or 3 will do. But the dudes at EIMAC say for no grid current/no drive power, passive grid ok.

The IF will always be 455 kHz (or some other fixed frequency),
so there's no point in measuring it.

The incoming RF will be too weak, and you don't want to take any
of it away. Anyhow, you'll be measuring several signals at once
(at frequencies close to each other) if you measure at an RF stage.
The IF stages pick out the exact one you're tuned to.

Measure the oscillator, and subtract 455 kHz from the reading.
Thus, when you are tuned to 10.000 MHz, the counter will read 10.455.

The really proper way to do it is to build a counter that will automatically
subtract 455 from the number to be displayed -- for example, by starting
at 999545 rather than at 000000 on each count.

I think G10 has been entirely replaced by FR4; they should be equivalent unless you particularly do not want fire resistance. You should be able to find surplus board material at many surplus places; see ads in "Electronics Now" for example (their expanded ad section appears only once every three or four months)

Cleaning out the shack and found a bunch of high voltage mica caps. They
range from .01MFD to .0005MFD. Voltage range from 1200 volts to 5KV.
All you builders out there, email your needs and I'll see if I can match
them up. I picked these up at hamfests over the last 20 years and always
refused to pay more than 50 cents each so that's what I'll let them go for.
Plus shipping of course. Email: raym@omnifest.uwm.edu Ray WB9ZIQ

Mike,

Building an L band oscillator using an LC network is not an approach you should take. There are various schemes for generating RF at these frequencies. One, tried and true approach is to design an oscillator at a lower frequency (let's say a 5th overtone at 100 MHz). After the oscillator, you would place a set of multipliers. These mults. could be BJT transistor type of X2 or X3, or the mult. could be an SRD type and you can filter the frequency you desire. These are standar techniques which have been used by me and others. In fact the beacon transmitter on the Telstar 4 spacecraft is designed in this way. (I had a hand in the box in a previous life).
A second approach would be to use a Dielectric Resonator Oscillator right at L band . Check Microwave Engineering by Pozar for design equation. This approach will require some good microstrip skills and access to a microwave board layour program.
If you have other questions I will try and help.

Actually, even for X band, where the tolerances get more difficult,
perfectly acceptable boards from an electrical viewpoint can be
made using dial calipers and sharp knife to remove "Scotch tape"
resist in just the right places with *lots* of patience. I happen
to have a few examples.

The difficulty with DROs seems to be finding a place to buy small
quantities of the resonators.

1578. HP 5360 "interpolator" info wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 1994-06-23 14:53:45 UTC
From: kbanke@qualcomm.com
Message-ID: <kbanke-230694065345@kbanke.qualcomm.com>
Source record: 117346

I am trying to keep a couple of HP 5360 computing counters operating for
Ham Radio uses but a common problem over time seems to be the
"interpolator" module for which the technical manual gives no information.
I suspect 20 years ago the technology was proprietary and the info was not
publicized. Does anyone have a schematic or other info on this module?
Any help would be greatly appreciated.

1579. new HAMCOM interface with optical isolation

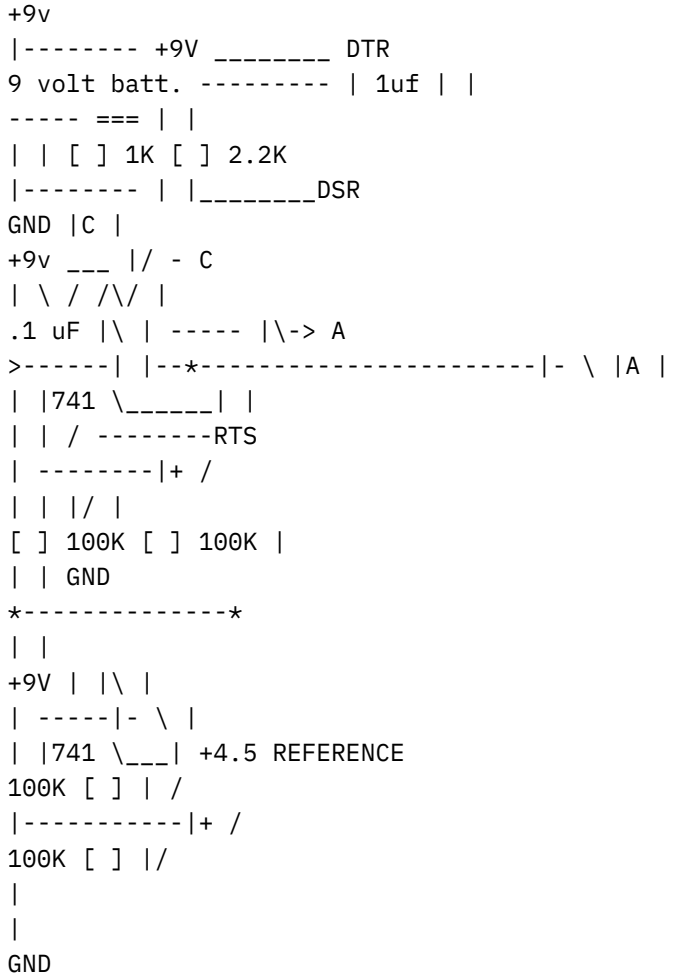
Newsgroup: rec.radio.amateur.homebrew
Date: 1994-06-23 15:09:39 UTC
From: copeland@metronet.com
Message-ID: <CruvG3.563@metronet.com>
Source record: 117317

Here are two opto circuit I've been playing with for HAMCOM/JVFAX.
They virtually eliminate all computer induced rfi. I've been using
a five foot serial cable and twenty foot audio cable with this
circuit and the results are truly remarkable with JVFAX.

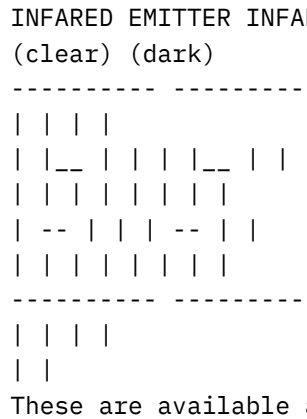
I've used the first circuit successfully, but recommend using the second.
The first can be built with common Radio Shack parts. The second requires
a little more uncommon LM358 and TIL181. The Radio Shack opto RECEIVER
is only rated at 20v but used at 24v and could eventually burn out.
It also may introduced problems since the +9v is not regulated and induces
error into the reference op amp output ... even though it seems to work well.

Perhaps some engineers out there may have some advice.

==========



==========

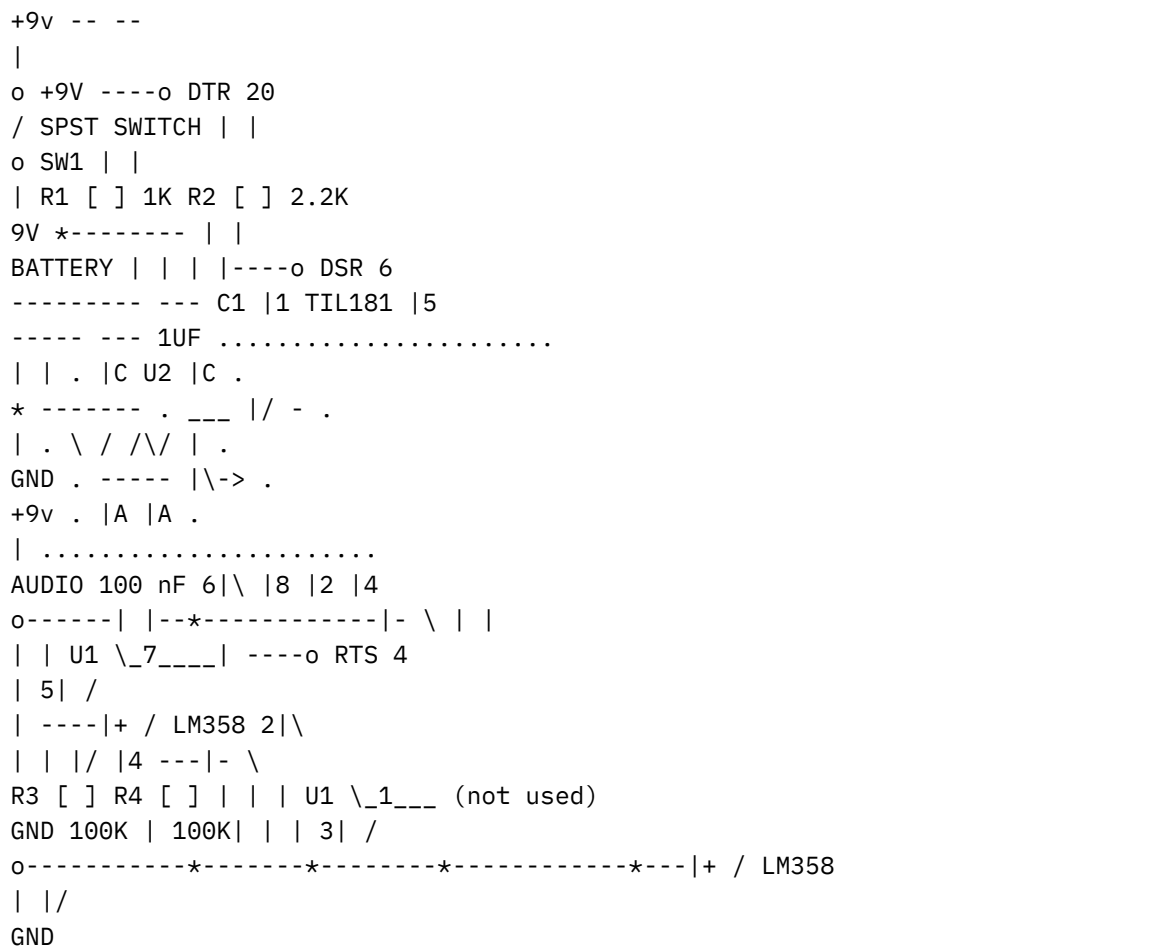


These are available at Radio Shack as a pair for $1.99 (#276-142).
This shows which is the Anode and which is the Cathode, not clear on
the package.

The LED and DETECTOR must be positioned right up against each other and
exactly aligned to get maximum light transfer. The sides with the little
lense like dots must be placed together.

==========

I'd recommend this second circuit for more stability and possibly accuracy.



```
================================================================================
| ** NOTE** |
| After constructing, measure LM358 pin 7 with no audio on the input. |
| It should be high (~8v), if it is low (~0v) it will drain the battery |
| in only 20 hours or less. |
| |
| To correct this: Disconnect R1 from +9v and reconnect to U1 pin 7. |
| Disconnect U1 pin 2 and reconnect to GND. |
| |
================================================================================
```

The LM358 is a single supply opamp and can be substituted with the LM2904, LM158, or LM258. (The dual supply 741 can not be used as a substitute.)

The opto isolator IC can be substitued for many other types. The 4N35 has been tested successfully. The discrete infared emitter/detector from Radio Shack has been tested successfully.

I tried to use a darlington opto (TIL113), but couldn't get it to work. A darlington opto circuit would only require 1.5ma average. That would make battery life about 133 hours. Maybe I'll try again later.

```
================================================================================
```
MORE NOTES:

The 9v battery could be substitued with a 9 or 12 vdc adapter. However I've found the clearest pictures occur when both the radio and HAMCOM are running off batteries ... at 6am 8).

A 9v battery should last about 50 hours while audio is present (assuming 200ma hours for a battery). If no audio is present the battery will last 400 hours.

The battery life could be a problem for people who leave HAMCOM running all night using the timed FAX option. Battery would only last a week.

If you have any advice or knowledge that could improve this, please let me know.

Has anyone else noticed that JDR seems to have picked up lots of neat lines? I was just flipping through their electronic components catalog and they've got about 6 pages of kits, including a 2m xcvr for $150. Case is extra (like I want a naked board...).

They've also got a pretty good selection of IC's including the MC1350 IF amp and the NE602... visible laser diode... cases...

Phone is 408-494-1400.

I don't work for them and I don't advertise for them. I DEFINITELY don't vouch for them. Just thought y'all might be interested...

-Bill VanRemmen, KA2WFJ
